#### Abstract

We introduce Refinement Reflection, a new framework for building SMT-based deductive verifiers. The key idea is to reflect the code implementing a user-defined function into the function's (output) refinement type. As a consequence, at uses of the function, the function definition is instantiated in the SMT logic in a precise fashion that permits decidable verification. Reflection allows the user to write equational proofs of programs just by writing other programs e.g. using pattern-matching and recursion to perform case-splitting and induction. Thus, via the propositions-as-types principle, we show that reflection permits the specification of arbitrary functional correctness properties. Finally, we introduce a proof-search algorithm called Proof by Logical Evaluation that uses techniques from model checking and abstract interpretation, to completely automate equational reasoning. We have implemented reflection in Liquid Haskell and used it to verify that the widely used instances of the Monoid, Applicative, Functor, and Monad typeclasses actually satisfy key algebraic laws required to make the clients safe, and have used reflection to build the first library that actually verifies assumptions about associativity and ordering that are crucial for safe deterministic parallelism.

## 1 INTRODUCTION

Deductive verifiers fall roughly into two camps. Satisfiability Modulo Theory (SMT) based verifiers (e.g. Dafny and $\mathrm{F}^{*}$ ) use fast decision procedures to automate the verification of programs that only require reasoning over a fixed set of theories like linear arithmetic, string, set and bitvector operations. These verifiers, however, encode the semantics of user-defined functions with universally-quantified axioms and use incomplete (albeit effective) heuristics to instantiate those

[^0]axioms. These heuristics make it difficult to characterize the kinds of proofs that can be automated, and hence, explain why a given proof attempt fails [30]. At the other end, we have Type-Theory (TT) based theorem provers (e.g. CoQ and AgDa) that use type-level computation (normalization) to facilitate principled reasoning about terminating user-defined functions, but which require the user to supply lemmas or rewrite hints to discharge proofs over decidable theories.

We introduce Refinement Reflection, a new framework for building SMT-based deductive verifiers, which permits the specification of arbitrary properties and yet enables complete, automated SMTbased reasoning about user-defined functions. In previous work, refinement types [17, 44] - which decorate basic types (e.g. Integer) with SMT-decidable predicates (e.g. \{v:Integer $\mid 0 \leq v \& \&$ $v<100\}$ ) - were used to retrofit so-called shallow verification, such as array bounds checking, into several languages: ML [6, 42, 63], C [16, 43], Haskell [56], TypeScript [59], and Racket [26]. In this work, we extend refinement types with refinement reflection, leading to the following three contributions.

1. Refinement Reflection Our first contribution is the notion of refinement reflection. To reason about user-defined functions, the function's implementation is reflected into its (output) refinementtype specification, thus converting the function's type signature into a precise description of the function's behavior. This simple idea has a profound consequence: at uses of the function, the standard rule for (dependent) function application yields a precise means of reasoning about the function (§ 4).
2. Complete Specification Our second contribution is a library of combinators that lets programmers compose sophisticated proofs from basic refinements and function definitions. Our proof combinators let programmers use existing language mechanisms, like branches (to encode case splits), recursion (to encode induction), and functions (to encode auxiliary lemmas), to write proofs that look very much like their pencil-and-paper analogues (§ 2). Furthermore, since proofs are literally just programs, we use the principle of propositions-as-types [62] (known as the Curry-Howard isomorphism [24]) to show that SMT-based verifiers can express any natural deduction proof, thus providing a pleasant implementation of natural deduction that can be used for pedagogical purposes (§3).
3. Complete Verification While equational proofs can be very easy and expressive, writing them out can quickly get exhausting. Our third contribution is Proof by Logical Evaluation (PLE) a new proof-search algorithm that automates equational reasoning. The key idea in PLE is to mimic type-level computation within SMT-logics by representing functions in a guarded form [19] and repeatedly unfolding function application terms by instantiating them with their definition corresponding to an enabled guard. We formalize a notion of equational proof and show that the above strategy is complete: i.e. it is guaranteed to find an equational proof if one exists. Furthermore, using techniques from the literature on Abstract Interpretation [18] and Model Checking [14], we show that the above proof search corresponds to a universal (or must) abstraction of the concrete semantics of the user-defined functions. Thus, since those functions are total, we obtain the pleasing guarantee that proof search terminates (§ 6).

We evaluate our approach by implementing refinement reflection and PLE in Liquid Haskell [56], thereby turning Haskell into a theorem prover. Repurposing an existing programming language allows us to take advantage of a mature compiler and an ecosystem of libraries, while keeping proofs and programs in the same language. We demonstrate the benefits of this conversion by proving typeclass laws. Haskell's typeclass machinery has led to a suite of expressive abstractions and optimizations which, for correctness, crucially require typeclass instances to obey key algebraic laws. We show how reflection and PLE can be used to verify that widely used instances of the Monoid, Applicative, Functor, and Monad typeclasses satisfy the respective laws. Finally, we use
reflection to create the first deterministic parallelism library that actually verifies assumptions about associativity and ordering that ensure determinism (§7).

Thus, our results demonstrate that Refinement Reflection and Proof by Logical Evaluation identify a new design for deductive verifiers which, by combining the complementary strengths of SMTand TT- based approaches, enables complete verification of expressive specifications spanning decidable theories and user defined functions.

## 2 OVERVIEW

We start with an overview of how SMT-based refinement reflection lets us write proofs as plain functions and how PLE automates equational reasoning.

### 2.1 Refinement Types

First, we recall some preliminaries about specification and verification with refinement types.
Refinement types are the source program's (here Haskell's) types refined with logical predicates drawn from an SMT-decidable logic [17, 44]. For example, we define Nat as the set of Integer values $v$ that satisfy the predicate $0 \leq v$ from the quantifier-free logic of linear arithmetic and uninterpreted functions (QF-UFLIA [5]):

```
type Nat = { v:Integer | 0 \leq v }
```

Specification \& Verification Throughout this section, to demonstrate the proof features we add to Liquid Haskell, we will use the textbook Fibonacci function which we type as follows.

```
fib :: Nat }->\mathrm{ Nat
fib 0 = 0
fib 1 = 1
fib n = fib (n-1) + fib (n-2)
```

To ensure termination, the input type's refinement specifies a pre-condition that the parameter must be Nat. The output type's refinement specifies a post-condition that the result is also a Nat. Refinement type checking automatically verifies that if fib is invoked with a non-negative Integer, then it terminates and yields a non-negative Integer.
Propositions We define a data type representing propositions as an alias for unit:

```
type Prop = ()
```

which can be refined with propositions about the code, e.g. that $2+2$ equals 4

```
type Plus_2_2 = { v: Prop | 2 + 2 = 4 }
```

For simplicity, in Liguid Haskell, we abbreviate the above to type Plus_2_2 = \{ $2+2=4$ \}.
Universal \& Existential Propositions Using the standard encoding of Howard [24], known as the Curry-Howard isomorphism, refinements encode universally-quantified propositions as dependent function types of the form:

```
type Plus_comm = x:Integer }->\textrm{y}:\mathrm{ Integer }->{x+y=y+x
```

As x and y refer to arbitrary inputs, any inhabitant of the above type is a proof that Integer addition commutes.
Refinements encode existential quantification via dependent pairs of the form:

```
type Int_up = n:Integer }->\mathrm{ (m::Integer, {n< m})
```

The notation ( $m:: t, t^{\prime}$ ) describes dependent pairs where the name $m$ of the first element can appear inside refinements of the second element. Thus, Int_up states the proposition that for every integer $n$, there exists one that is larger than $n$.

While quantifiers cannot appear directly inside the refinements, dependent functions and pairs allow us to specify quantified propositions. One limitation of this encoding is that quantifiers cannot exist inside refinement's logical connectives (like $\wedge$ and $\vee$ ). In § 3, we describe how to encode logical connectives using data types, e.g. conjunction as a product and disjunction as a union, how to specify arbitrary, quantified propositions using refinement types, i.e. have complete specifications, and how to verify those propositions using refinement type checking.
Proofs We prove the above propositions by writing Haskell programs, for example

```
plus_2_2 :: Plus_2_2 plus_comm :: Plus_comm int_up :: Int_up
plus_2_2 = () plus_comm = \x y -> () int_up = \n -> (n+1,())
```

Standard refinement typing reduces the above to the respective verification conditions (VCs)

$$
\text { true } \Rightarrow 2+2=4 \quad \forall x, y . \text { true } \Rightarrow x+y=y+x \quad \forall n . n<n+1
$$

which are easily deemed valid by the SMT solver, allowing us to prove the respective propositions.
Soundness and Lazy Evaluation Readers familiar with Haskell's lazy semantics may be concerned that "bottom", which inhabits all types, makes our proofs suspect. Fortunately, as described in Vazou et al. [56], Liquid Haskell, by default, checks that user defined functions provably terminate and are total (i.e. return non-bottom values, and do not throw any exceptions), which makes our proofs sound. Liquid Haskell checks that each function is terminating using a termination metric i.e. a natural number that decreases at each recursive call. For instance, if we generalize the signature of fib to Integers, as shown below, then Liguid Haskell reports a termination error:

```
fib :: n:Integer }->\mathrm{ Integer
```

Liquid Haskell generates a type error in the definition of fib since in the recursive calls fib ( $\mathrm{n}-1$ ) and fib ( $n-2$ ) the arguments $n-1$ and $n-2$ cannot be proved to be non-negative and less than $n$. Both these proof obligations are satisfied when the domain of fib is restricted to natural numbers.

```
fib :: n:Nat -> Nat / [n]
```

The above type signature is explicitly annotated with the user specified termination metric / [n] declaring that n is the decreasing natural number. Liquid Haskell heuristically assumes that the termination metric is always the first argument of the function (that can be mapped to natural numbers), thus, the above explicit termination metric can be omitted.

Not all Haskell functions terminate. The lazy annotation deactivates termination checking, e.g. for the the diverge function shown below. Haskell terms marked as lazy could unsoundly be used as proof terms, much like CoQ's unsoundness with respect to Admitted. For example, the following is accepted by Liquid Haskell

```
lazy diverge
diverge :: x:Integer }->{x=0
diverge x = diverge x
```

Totality Checking Liquid Haskell further checks that all user-specified functions are totally defined. For instance the below definition

```
fibPartial 0 = 0
fibPartial 1 = 1
```

generates a totality error. The above definition is completed, by GHC, with an error invocation

```
fibPartial 0 = 0
fibPartial 1 = 1
fibPartial _ = error "undefined"
```

Thus, to check totality, Liquid Haskell simply ascribes the precondition false to error

```
error :: { v:String | false } }->\textrm{a
```

Thus, to typecheck fibPartial, Lieuid Haskell needs to prove that the call to error is dead-code, i.e. happens under an inconsistent environment. As this check fails, Liquid Haskell generates a totality error. As with termination checking, Liquid Haskell provides an unsound error function unsoundError with no false precondition.

In the sequel (and in our evaluation) we assume that proof terms are generated without any unsound uses of lazy or unsafeError. However, note that lazy, diverging functions can be soundly verified, and diverging code can soundly co-exist with terminating proof terms: we refer the reader to Vazou et al. [56] for details.

### 2.2 Refinement Reflection

Suppose we wish to prove properties about the fib function, e.g. that $\{$ fib $2=1\}$. Standard refinement type checking runs into two problems. First, for decidability and soundness, arbitrary user-defined functions cannot belong in the refinement logic, i.e. we cannot refer to fib in a refinement. Second, the only specification that a refinement type checker has about fib is its type Nat $\rightarrow$ Nat which is too weak to verify \{fib $2=1\}$. To address both problems, we reflect fib into the logic which sets the three steps of refinement reflection in motion.
Step 1: Definition The annotation creates an uninterpreted function fib :: Integer $\rightarrow$ Integer in the refinement logic. By uninterpreted, we mean that the logical fib is not connected to the program function fib; in the logic, fib only satisfies the congruence axiom $\forall n, m . n=m \Rightarrow$ fib $n=f i b m$. On its own, the uninterpreted function is not terribly useful: we cannot check \{fib $2=1\}$ as the SMT solver cannot prove the VC true $\Rightarrow$ fib $2=1$ which requires reasoning about fib's definition.
Step 2: Reflection In the next key step, we reflect the definition of fib into its refinement type by automatically strengthening the user defined type for fib to:

```
fib :: n:Nat -> { v:Nat | v = fib n && fibP n }
```

where fibP is an alias for a refinement automatically derived from the function's definition:

```
fibP n = n == 0 f fib n = 0
    ^n== 1 m fib n = 1
    ^n > 1 m fib n = fib (n-1) + fib (n-2)
```

Step 3: Application With the reflected refinement type, each application of fib in the code automatically unfolds the definition of fib once in the logic. We prove \{fib $2=1\}$ by:

```
pf_fib2 :: { fib 2 = 1 }
pf_fib2 = let { t0 = fib 0; t1 = fib 1; t2 = fib 2 } in ()
```

We write in bold red, $f$, to highlight places where the unfolding of $f$ 's definition is important. Via refinement typing, the above yields the following VC that is discharged by SMT, even though fib is uninterpreted:

```
(fibP 0 ^ fibP 1 ^ fibP 2) =>(fib 2=1)
```

The verification of pf_fib2 relies merely on the fact that fib is applied to (i.e. unfolded at) 0,1 , and 2. The SMT solver automatically combines the facts, once they are in the antecedent. Thus, the following is also verified:

```
pf_fib2' :: {v:[Nat] | fib 2 = 1 }
pf_fib2' = [ fib 0, fib 1, fib 2 ]
```

In the next subsection, we will continue to use explicit, step-by-step proofs as above, but we will introduce tools for proof composition. Then, in § 2.4 we will show how to eliminate unnecessary details from such proofs, using Proof by Logical Evaluation (PLE).

### 2.3 Equational Proofs

We can structure proofs to follow the style of calculational or equational reasoning popularized in classic texts [8,20] and implemented in Agda [34] and Dafny [31]. To this end, we have developed a library of proof combinators that permits reasoning about equalities and linear arithmetic.
"Equation" Combinators We equip Liquid HASKell with a family of equation combinators, $\odot$, for logical operators in the theory QF-UFLIA, $\odot \in\{=, \neq, \leq,<, \geq,>\}$. In Haskell code, to avoid collisions with existing operators, we further append a colon ":" to these operators, so that "=" becomes the Haskell operator ( $=:$ ). The refinement type of $\odot$ requires that $x \odot y$ holds and then ensures that the returned value is equal to $x$. For example, we define (=:) as:

```
(=:) :: x:a }->\textrm{y}:{\textrm{a}|\textrm{x}=\textrm{y}}->{\mp@code{v:a | v = x }
x =: _ = x
```

and use it to write the following equational proof:

```
fib2_1 :: { fib 2 = 1 }
fib2_1 = fib 2 =: fib 1 + fib 0 =: 1 ** QED
```

where ** QED constructs proof terms by casting expressions to Prop in a post-fix fashion.

```
data QED = QED (**) :: a }->\mathrm{ QED }->\mathrm{ Prop
_ ** QED = ()
```

Proof Arguments Often, we need to compose lemmas into larger theorems. For example, to prove fib $3=2$ we may wish to reuse fib2_1 as a lemma. We do so by defining a variant of (=:), written as (=?), that takes an explicit proof argument:

$$
\begin{aligned}
& (=?):: x: a \rightarrow y: a \rightarrow\{\operatorname{Prop} \mid x=y\} \rightarrow\{v: a \mid v=x\} \\
& \mathrm{x}=\text { ? _ _ }=\mathrm{x}
\end{aligned}
$$

We use the (=?) combinator to prove that fib $3=2$.

```
fib3_2 :: { fib 3 = 2 }
fib3_2 = (fib 3 =: fib 2 + fib 1 =? 2 $ fib2_1) ** QED
```

Here fib 2 is not important to unfold, because fib2_1 already provides the same information.
"Because" Combinators Observe that the proof term fib3_2 needs parentheses, since Haskell's (\$) operator has the lowest (i.e. 0) precedence. To omit parentheses in proof terms, we define a "because" combinator that operates exactly like Haskell's (\$) operator, but has the same precedence as the proof combinators ( $=$ :) and (=?).

```
(\because) :: (Prop }->\mathrm{ a) }->\mathrm{ Prop }->\mathrm{ a
f}\becausey=f
```

We use the "because" combinator to remove the parentheses from the proof term fib3_2.

```
fib3_2 :: { fib 3 = 2 }
fib3_2 = fib 3 =: fib 2 + fib 1 =? 2 \becausefib2_1 ** QED
```

Optional Proof Arguments Finally, we unify both combinators (=:) and (=?) using type classes to define the class method (=.) that takes an optional proof argument, and generalize such definitions for each operator in $\odot$. We define the class OptEq to have one method ( $=$. ) that takes two arguments of type $a$, to be compared for equality, and returns a value of type $r$.

```
class OptEq a r where
    (=.) :: a }->\textrm{a}->\textrm{r
```

When instantiating the result type to be the same as the argument type $a,(=$.$) behaves as (=: ).$

```
instance (a~b) = OptEq a b where
    (=.) :: x:a }->{y:a|x=y}->{v:b | v = x }
```

When the result type is instantiated to be a function that given a proof term Prop returns the argument type $a$, (=.) behaves exactly as (=?).

```
instance (a~b) = OptEq a (Prop }->\textrm{b}\mathrm{ ) where
    (=.) :: x:a }->\textrm{y}:\textrm{a}->{{\operatorname{Prop | x = y } }->{v:a|v=x
```

Thus, (=.) takes two arguments to be compared for equality and, optionally, a proof term argument. With this, the proof term fib3_2 is simplified to

```
fib3_2 :: { fib 3 = 2 }
fib3_2 = fib 3 =. fib 2 + fib 1 =. 2 \becauseffib2_1 ** QED
```

Arithmetic and Ordering Next, lets see how we can use arithmetic and ordering to prove that fib is (locally) increasing, i.e. for all $n$, fib $n \leq f i b(n+1)$.

```
type Up f = n:Nat }->{f\textrm{n}\leq\textrm{f}(\textrm{n}+1)
fibUp :: Up fib
fibUp 0 = fib 0 <. fib 1 ** QED
fibUp 1 = fib 1 土. fib 1 + fib 0 =. fib 2 ** QED
fibUp n = fib n \leq. fib n + fib (n-1) =. fib (n+1) ** QED
```

Case Splitting The proof fibUp works by splitting cases on the value of $n$. In the cases 0 and 1 , we simply assert the relevant inequalities. These are verified as the reflected refinement unfolds the definition of fib at those inputs. The derived VCs are (automatically) proved as the SMT solver concludes $0<1$ and $1+0 \leq 1$ respectively. When $n$ is greater than one, fib $n$ is unfolded to fib ( $n-1$ ) + fib ( $n-2$ ), which, as fib ( $n-2$ ) is non-negative, completes the proof.
Induction \& Higher Order Reasoning Refinement reflection smoothly accommodates induction and higher-order reasoning. For example, let's prove that every function $f$ that increases locally (i.e. $f z \leq f(z+1)$ for all $z$ ) also increases globally (i.e. $f x \leq f y$ for all $x<y$ )

```
type Mono = f:(Nat }->\mathrm{ Integer) }->\mathrm{ Up f }->\textrm{x}:Nat -> y:{x<y } -> { f x \leq f y 
fMono :: Mono / [y]
fMono f up x y
    | x+1 == y = f x \leq.f (x+1) \becauseup x \leq.f y ** QED
    | x+1<y=f x \leq.f (y-1) \becausefMono f up x (y-1) \leq.f y \becauseup (y-1) ** QED
```

We prove the theorem by induction on $y$ as specified by the annotation / [y] which states that $y$ is a well-founded termination metric that decreases at each recursive call [56]. If $x+1==y$, then we call the up $x$ proof argument. Otherwise, $x+1<y$, and we use the induction hypothesis i.e. apply
fMono at $y-1$, after which transitivity of the less-than ordering finishes the proof. We can apply the general fMono theorem to prove that fib increases monotonically:

```
fibMono :: n:Nat }->\textrm{m}:{\textrm{n}<\textrm{m}}->{\mp@code{fib n \leq fib m }
fibMono = fMono fib fibUp
```

### 2.4 Complete Verification: Automating Equational Reasoning

While equational proofs can be very easy, writing them out can quickly get exhausting. Lets face it: fib3_2 is doing rather a lot of work just to prove that fib 3 equals 2! Happily, the calculational nature of such proofs allows us to develop the following proof search algorithm PLE that is inspired by model checking [14]

- Guard Normal Form: First, as shown in the definition of fibP in § 2.2, each reflected function is transformed into a guard normal form $\wedge_{i}\left(p_{i} \Rightarrow f(\bar{x})=b_{i}\right)$ i.e. a collection of guards $p_{i}$ and their corresponding definition $b_{i}$.
- Unfolding: Second, given a VC of the form $\Phi \Rightarrow p$, we iteratively unfold function application terms in $\Phi$ and $p$ by instantiating them with the definition corresponding to an enabled guard, where we check enabled-ness by querying the SMT solver. For example, given the VC true $\Rightarrow$ fib $3=2$, the guard $3>1$ of the application fib 3 is trivially enabled, i.e. is true, hence we strengthen the hypothesis $\Phi$ with the equality fib $3=\mathrm{fib}(3-1)+\mathrm{fib}(3-2)$ corresponding to unfolding the definition of fib at 3 .
- Fixpoint: We repeat the unfolding process until either the VC is proved or we have reached a fixpoint, i.e. no further unfolding is enabled. For example, the fixpoint computation of fib 3 unfolds the definition of fib at $3,2,1$, and 0 and then stops as no further guards are enabled.
Automatic Equational Reasoning In § 6 we formalize a notion of equational proof and show that the proof search procedure PLE enjoys two key properties. First, that it is guaranteed to find an equational proof if one can be constructed from unfoldings of function definitions. (The user must still provide instantiations of lemmas and induction hypotheses.) Second, that under certain conditions readily met in practice, it is guaranteed to terminate. These two properties allow us to use PLE to predictably automate proofs: the programmer needs only to supply the relevant induction hypotheses or helper lemma applications. The remaining long chains of calculations are performed automatically via SMT-based PLE. That is, the user must provide case statements and the recursive structure, but can elide the long chains of $=$. applications. To wit, with complete proof search, the proofs of § 2.3 shrink to:

```
fib3_2 :: {fib 3 = 2} fMono :: Mono / [y]
fib3_2 = () fMono f up x y
    | x+1 == y = up x
    | x+1 < y = up (y-1) &&& fMono up x (y-1)
```

where the combinator $\mathrm{p} \& \& \& \mathrm{q}=()$ inserts the propositions p and q to the VC hypothesis.
PLE vs. Axiomatization Existing SMT based verifiers like Dafny [29] and F* [52] use the classical axiomatic approach to verify assertions over user-defined functions like fib. In these systems, the function is encoded in the logic as a universally quantified formula (or axiom): $\forall n$. fibP $n$ after which the SMT solver may instantiate the above axiom at $3,2,1$ and 0 in order to automatically prove \{fib $3=2\}$.

The automation offered by axioms is a bit of a devil's bargain, as axioms render VC checking undecidable, and in practice automatic axiom instantiation can easily lead to infinite "matching loops". For example, the existence of a term fib $n$ in a VC can trigger the above axiom, which may then produce the terms $\operatorname{fib}(n-1)$ and fib ( $n-2$ ), which may then recursively give rise to further

```
app_assoc :: AppendAssoc
app_assoc [] ys zs
    = ([] ++ ys) ++ zs
    =. ys ++ zs
    =. [] ++ (ys ++ zs) ** QED
app_assoc (x:xs) ys zs
    = ((x : xs) ++ ys) ++ zs
    =. (x : (xs ++ ys)) ++ zs
    =. x :((xs ++ ys) ++ zs)
    \becauseapp_assoc xs ys zs
    =. x : (xs ++ (ys ++ zs))
    =. (x : xs) ++ (ys ++ zs) ** QED
```

$\begin{array}{lr}\text { app_assoc } & : \text { : AppendAssoc } \\ \text { app_assoc [] } & \text { ys zs }=() \\ \text { app_assoc (x:xs) ys zs }=\text { app_assoc xs ys zs }\end{array}$

| app_right_id | $:$ AppendNilId |
| :--- | :--- |
| app_right_id [] | $=()$ |
| app_right_id (x:xs) | $=$ app_right_id xs |

| map_fusion | $:$ : MapFusion |
| :--- | :--- |
| map_fusion f g [] | $=$ () |
| map_fusion f g $(x: x s)$ | $=$ map_fusion f g xs |

Fig. 1. (L) Equational proof of append associativity.
(R) PLE proof, also of append-id and map-fusion.
instantiations ad infinitum. To prevent matching loops an expert must carefully craft "triggers" or alternatively, provide a "fuel" parameter that bounds the depth of instantiation [1]. Both these approaches ensure termination, but can cause the axiom to not be instantiated at the right places, thereby rendering the VC checking incomplete. The incompleteness is illustrated by the following example from the Dafny benchmark suite [32]

```
pos n | n<0 = 0 test :: y:{y>5} -> {pos n = 3 + pos (n-3)}
    | otherwise = 1 + pos (n-1) test _ = ()
```

Dafny (and $\mathrm{F}^{*}$ 's) fuel-based approach fails to check the above, when the fuel value is less than 3 . One could simply raise-the-fuel-and-try-again but at what point does the user know when to stop? In contrast, PLE (1) does not require any fuel parameter, (2) is able to automatically perform the required unfolding to verify this example, and (3) is guaranteed to terminate.

### 2.5 Case Study: Laws for Lists

Reflection and PLE are not limited to integers. We end the overview by showing how they verify textbook properties of lists equipped with append $(++)$ and map functions:

```
reflect (++) :: [a] \(\rightarrow\) [a] \(\rightarrow\) [a] reflect map :: \((a \rightarrow b) \rightarrow[a] \rightarrow[b]\)
[] ++ ys = ys \(\quad \operatorname{map} f[] \quad=[]\)
( \(x: x s\) ) ++ ys = \(x:(x s++y s) \quad \operatorname{map} f(x: x s)=f x: m a p f x s\)
```

In § 5.1 we will describe how the reflection mechanism illustrated via fibP is extended to account for ADTs using SMT-decidable selection and projection operations, which reflect the definition of $x s++$ ys into the refinement as: if isNil $x s$ then $y s$ else sel1 $x s$ : ( $\operatorname{sel} 2 x s++y s)$. We require an explicit reflect annotation as not all Haskell functions can be reflected into logic, either because it is unsound to do so (e.g. due to divergence) or because of limitations of our current implementation. Recall that Liguid Haskell verifies that all reflected functions, like (++) and map here, are total [56] and rejects the code otherwise.
Laws We can specify various laws about lists with refinement types. For example, the below laws state that (1) appending to the right is an identity operation, (2) appending is an associative operation, and (3) map distributes over function composition:

```
type AppendNilId = xs:_ -> { xs ++ [] = xs }
type AppendAssoc = xs:_ }->\mathrm{ ys:__ }->\mathrm{ zs:_ }->\mathrm{ { { xs ++ (ys ++ zs) = (xs ++ ys) ++ zs }
type MapFusion = f:_ }->\textrm{g}:_ -> xs:_ -> { map (f.g) xs = map f (map g xs) }
```

Fig. 2. Proofs that swap is idempotent with Coq, Agda, Dafny and PLE.

Proofs On the right in Figure 1 we show the proofs of these laws using PLE, which should be compared to the classical equational proof e.g. by Wadler [61], shown on the left. With PLE, the user need only provide the high-level structure - the case splits and invocations of the induction hypotheses - after which PLE automatically completes the rest of the equational proof. Thus using SMT-based PLE, app_assoc shrinks down to its essence: an induction over the list xs. The difference is even more stark with map_fusion whose full equational proof is omitted, as it is twice as long.
PLE vs. Normalization The proofs in Figure 1 may remind readers familiar with Type-Theory based proof assistants (e.g. CoQ or AGDA) of the notions of type-level normalization and rewriting that permit similar proofs in those systems. While our approach of PLE is inspired by the idea of type level computation, it differs from it in two significant ways. First, from a theoretical point of view, SMT logics are not equipped with any notion of computation, normalization, canonicity or rewriting. Instead, our PLE algorithm shows how to emulate those ideas by asserting equalities corresponding to function definitions (Theorem 6.10). Second, from a practical perspective, the combination of (decidable) SMT-based theory reasoning and PLE's proof search can greatly simplify verification. For example, consider the swap function from Appel [2]'s CoQ textbook:

```
swap :: [Integer] }->\mathrm{ [Integer]
swap (x1:x2:xs) = if x1 > x2 then x2:x1:x2 else x1:x2:xs
swap xs = xs
```

In Figure 2 we show four proofs that swap is idempotent: Appel's proof using CoQ (simplified by the use of a hint database and the arithmetic tactic omega), its variant in Agda (for any Decidable Partial Order), the PLE proof, and a proof using the DAFNY verifier. It is readily apparent that PLE's proof search, working hand-in-glove with SMT-based theory reasoning, makes proving the result trivial in comparison to CoQ or Agda. Of course, proof assistants like Agda, CoQ, and Isabelle emit easily checkable certificates and have decades-worth of tactics, libraries, and proof scripts that enable large scale proof engineering. On the other hand, Dafny's fuel-based axiom instantiation automatically unfolds the definition of swap twice, thereby completing the proof without any user input. These heuristics are orthogonal to PLE and can be combined with it, if the user wishes to trade off predictability for even more automation.
Summary We saw an overview of an SMT-automated refinement type checker that achieves SMTdecidable checking by restricting verification conditions to be quantifier-free and hence, decidable. In existing SMT-based verifiers (e.g. DAFNy) there are two main reasons to introduce quantifiers, namely (1) to express quantified specifications and (2) to encode the semantics of user-defined

|  | Logical Formula | Refinement Type |
| ---: | :---: | :---: |
| Native Terms | e | $\{e\}$ |
| Implication | $\phi_{1} \Rightarrow \phi_{2}$ | $\phi_{1} \rightarrow \phi_{2}$ |
| Negation | $\neg \phi$ | $\phi \rightarrow\{$ False $\}$ |
| Conjunction | $\phi_{1} \wedge \phi_{2}$ | $\left(\phi_{1}, \phi_{2}\right)$ |
| Disjunction | $\phi_{1} \vee \phi_{2}$ | Either $\phi_{1} \phi_{2}$ |
| Forall | $\forall x \cdot \phi$ | $x: \tau \rightarrow \phi$ |
| Exists | $\exists x \cdot \phi$ | $(x:: \tau, \phi)$ |

Fig. 3. Mapping from logical predicates to quantifier-free refinement types. $\{e\}$ abbreviates $\{v: \operatorname{Prop} \mid e\}$. Function binders are not relevant for negation and implication, and hence, elided.
functions. Next, we use propositions-as-types to encode quantified specifications and in § 4 we show how to encode the semantics of user-defined functions via refinement reflection.

## 3 EMBEDDING NATURAL DEDUCTION WITH REFINEMENT TYPES

In this section we show how user-provided quantified specifications can be naturally encoded using $\lambda$-abstractions and dependent pairs to encode universal and existential quantification, respectively. Proof terms can be generated using the standard natural deduction derivation rules, following Propositions as Types [62] (also known as the Curry-Howard isomorphism [24]). What is new is that we exploit this encoding to show for the first time that a refinement type system can represent any proof in Gentzen's natural deduction [23] while still taking advantage of SMT decision procedures to automate the quantifier-free portion of natural deduction proofs. For simplicity, in this section we assume all terms are total.

### 3.1 Propositions: Refinement Types

Figure 3 maps logical predicates to types constructed over quantifier-free refinements.
Native terms Native terms consist of all of the (quantifier-free) expressions of the refinement languages. In $\S 4$ we formalize refinement typing in a core calculus $\lambda^{R}$ where refinements include (quantifier-free) terminating expressions.

Boolean connectives Implication $\phi_{1} \Rightarrow \phi_{2}$ is encoded as a function from the proof of $\phi_{1}$ to the proof of $\phi_{2}$. Negation is encoded as an implication where the consequent is False. Conjunction $\phi_{1} \wedge \phi_{2}$ is encoded as the pair ( $\phi_{1}, \phi_{2}$ ) that contains the proofs of both conjuncts and disjunction $\phi_{1} \vee \phi_{2}$ is encoded as the sum type Either that contains the proofs of one of the disjuncts, i.e. where data Either a b = Left a | Right b.

Quantifiers Universal quantification $\forall x . \phi$ is encoded as lambda abstraction $x: \tau \rightarrow \phi$ and eliminated by function application. Existential quantification $\exists x . \phi$ is encoded as a dependent pair ( $\mathrm{x}:: \tau, \phi$ ) that contains the term $x$ and a proof of a formula that depends on $x$. Even though refinement type systems do not traditionally come with explicit syntax for dependent pairs, one can encode dependent pairs in refinements using abstract refinement types [55] which do not add extra complexity to the system. Consequently, we add the syntax for dependent pairs in Figure 3 as syntactic sugar for abstract refinements.

### 3.2 Proofs: Natural Deduction

We overload $\phi$ to be both a proposition and a refinement type. We connect these two meanings of $\phi$ by using the Propositions as Types [62], to prove that if there exists an expression (or proof term) with refinement type $\phi$, then the proposition $\phi$ is valid.

We construct proofs terms using Gentzen's natural deduction system [23], whose rules map directly to refinement type derivations. The rules for natural deduction arise from the propositions-as-types reading of the standard refinement type checking rule (to be defined in §4) $\Gamma \vdash e: \phi$ as " $\phi$ is provable under the assumptions of $\Gamma$ ". We write $\Gamma \vdash_{N D} \phi$ for Gentzen's natural deduction judgment "under assumption $\Gamma$, proposition $\phi$ holds". Then, each of Gentzen's logical rules can be recovered from the rules in Figure 5 by rewriting each judgment $\Gamma \vdash e: \phi$ of $\lambda^{R}$ as $\Gamma \vdash_{N D} \phi$. For example, conjunction and universal elimination can be derived as:

$$
\frac{\Gamma \vdash_{N D} \phi_{1} \vee \phi_{2} \quad \Gamma, \phi_{1} \vdash_{N D} \phi \quad \Gamma, \phi_{2} \vdash_{N D} \phi}{\Gamma \vdash_{N D} \phi} \vee-\mathrm{E} \frac{\Gamma \vdash_{N D} e_{x} \text { term } \quad \Gamma \vdash_{N D} \forall x \cdot \phi}{\Gamma \vdash_{N D} \phi\left[x / e_{x}\right]} \forall-\mathrm{E}
$$

Programs as Proofs As Figure 5 directly maps natural deduction rules to derivations that are accepted by refinement typing, we conclude that if there exists a natural deduction derivation for a proposition $\phi$, then there exists an expression that has the refinement type $\phi$.

Theorem 3.1. If $\Gamma \vdash_{N D} \phi$, then we can construct an e such that $\Gamma \vdash e: \phi$.
Note that our embedding is not an isomorphism, since the converse of Theorem 3.1 does not hold. As a counterexample, the law of the excluded middle can be proved in our system (i.e. we can construct an Either term $e$, so that $p:\{$ Bool $\mid$ True $\} \vdash e: p \vee \neg p$ ), but cannot be proved using natural deduction (i.e. $\{$ True $\} \nvdash_{N D} p \vee \neg p$ ). The reason for that is that our system is using the classical logic of the SMTs, which includes the law of the excluded middle. On the contrary, in intuitionistic systems that also encode natural deduction (e.g. Coo, IDris, NuPRL) the law of the excluded middle should be axiomatized.

### 3.3 Examples

Next, we illustrate our encoding with examples of proofs for quantified propositions ranging from textbook logical tautologies, properties of datatypes like lists, and induction on natural numbers.
Natural Deduction as Type Derivation We illustrate the mapping from natural deduction rules to typing rules in Figure 4 which uses typing judgments to express Gentzen's proof of the proposition

$$
\phi \equiv(\exists x \cdot \forall y \cdot(p x y)) \Rightarrow(\forall y \cdot \exists x \cdot(p x y))
$$

Read bottom-up, the derivation provides a proof of $\phi$. Read top-down, it constructs a proof of the formula as the term $\lambda e y$.case $e$ of $\left\{\left(x, e_{x}\right) \rightarrow\left(x, e_{x} y\right)\right\}$. This proof term corresponds directly to the following Haskell expression that typechecks with type $\phi$.

```
exAll :: p:(a -> a -> Bool) }->\mathrm{ (x::a, y:a }->{pxy})->y:a->(x::a, {p x y})
exAll _ = \e y }->\mathrm{ case e of {(x, ex) }->\mathrm{ (x, ex y)}
```

SMT-aided proofs The great benefit of using refinement types to encode natural deduction is that the quantifier-free portions of the proof can be automated via SMTs. For every quantifier-free proposition $\phi$, you can convert between $\{\phi\}$, where $\phi$ is treated as an SMT-proposition and $\phi$, where $\phi$ is treated as a type; and this conversion goes both ways. For example, let $\phi \equiv p \wedge(q \vee r)$. Then flatten converts from $\phi$ to $\{\phi\}$ and expand the other way, while this conversion is SMT-aided.

```
flatten :: p:_ }->\textrm{q}\mp@subsup{:}{_}{}->\textrm{r}:_->({p}, Either {q} {r}) -> {p && (q || r)
flatten (pf, Left qf) = pf &&& qf
flatten (pf, Right rf) = pf &&& rf
```

Fig. 4. Proof of $(\exists x . \forall y \cdot(p x y)) \Rightarrow(\forall y . \exists x \cdot(p x y))$ where $\phi_{e} \equiv \exists x . \forall y \cdot(p x y), \phi_{x} \equiv \forall y \cdot(p x y)$.

```
expand proof | q = (proof, Left proof)
expand proof | r = (proof, Right proof)
```

Distributing Quantifiers Next, we construct the proof terms needed to prove two logical properties: that existentials distribute over disjunctions and foralls over conjunctions, i.e.

$$
\begin{align*}
& \phi_{\exists} \equiv(\exists x \cdot p x \vee q x) \Rightarrow((\exists x \cdot p x) \vee(\exists x \cdot q x))  \tag{1}\\
& \phi_{\forall} \equiv(\forall x \cdot p x \wedge q x) \Rightarrow((\forall x \cdot p x) \wedge(\forall x \cdot q x)) \tag{2}
\end{align*}
$$

The specification of these properties requires nesting quantifiers inside connectives and vice versa. The proof of $\phi_{\exists}$ (1) proceeds by existential case splitting and introduction:

```
exDistOr :: p:_ -> q:_ -> (x::a, Either {p x} {q x})
    Gither (x::a, {p x}) (x::a, {q x})
exDistOr _ _ (x, Left px) = Left (x, px)
exDistOr _ _ (x, Right qx) = Right (x, qx)
```

Dually, we prove $\phi_{\forall}(2)$ via a $\lambda$-abstraction and case spitting inside the conjunction pair:

```
allDistAnd :: p:_ }->\textrm{q}:_ -> (x:a -> ({p x}, {q x}))
    ->((x:a->{p x}), (x:a->{q x }))
allDistAnd _ _ andx = ( (\x -> case andx x of (px, _) -> px)
    , (\x }->\mathrm{ case andx }x\mathrm{ of (_, qx) }->qx) 
```

The above proof term exactly corresponds to its natural deduction proof derivation but using SMT-aided verification can get simplified to the following

```
allDistAnd _ _ andx = (pf, pf)
    where pf x = case andx x of (px, py) }->\textrm{px &&& py
```

Properties of User Defined Datatypes As $\phi$ can describe properties of data types like lists, we can prove properties of such types, e.g. that for every list xs, if there exists a list ys such that $x s==y s++y s$, then $x s$ has even length.

$$
\phi \equiv \forall x s .((\exists y s . x s=y s++y s) \Rightarrow(\exists n .1 \mathrm{en} x s=n+n))
$$

The proof (evenLen) proceeds by existential elimination and introduction and uses the lenAppend lemma, which in turn uses induction on the input list and PLE to automate equational reasoning.

```
evenLen :: xs:[a]->(ys::[a],{xs = ys ++ ys}) }->\mathrm{ (n::Int,{len xs = n+n})
evenLen xs (ys,pf) = (len ys, lenAppend ys ys &&& pf)
```

53:14 N. Vazou, A. Tondwalkar, V. Choudhury, R. G. Scott, R. R. Newton, P. Wadler, and R. Jhala

$$
\begin{aligned}
& \Gamma \vdash \text { fst } e: \phi_{1} \\
& \frac{\Gamma \vdash \text { snd } e: \phi_{2}}{\Gamma \vdash e:\left(\phi_{1}, \phi_{2}\right)} \wedge-\mathrm{I} \\
& \frac{\Gamma \vdash e_{1}: \phi_{1}}{\Gamma \vdash \text { Left } e_{1}: \text { Either } \phi_{1} \phi_{2}} \vee \text {-L-I } \\
& \frac{\Gamma \vdash e_{1}: \phi_{2}}{\Gamma \vdash \text { Right } e_{2}: \text { Either } \phi_{1} \phi_{2}} \text { V-R-I } \\
& \frac{\Gamma, x: \phi_{x}+e: \phi}{\Gamma \vdash \lambda x . e: \phi_{x} \rightarrow \phi} \Rightarrow-\mathrm{I} \\
& \frac{\Gamma \vdash e:\left(\phi_{1}, \phi_{2}\right)}{\Gamma \vdash f \mathrm{ft} e: \phi_{1}} \wedge \text {-L-E } \\
& \Gamma \vdash e: \text { Either } \phi_{1} \phi_{2} \\
& \frac{\Gamma, x_{1}: \phi_{1} \vdash e_{1}: \phi \quad \Gamma, x_{2}: \phi_{2} \vdash e_{2}: \phi}{\Gamma \vdash \text { case } e \text { of }\left\{\text { Left } x_{1} \rightarrow e_{1} ;\right.} \vee \text {-E } \\
& \text { Right } \left.x_{2} \rightarrow e_{2}\right\}: \phi \\
& \frac{\Gamma \vdash e: \phi_{x} \rightarrow \phi \quad \Gamma \vdash e_{x}: \phi_{x}}{\Gamma \vdash e e_{x}: \phi} \Rightarrow-\mathrm{E} \\
& \frac{\Gamma, x: \tau \vdash e: \phi}{\Gamma \vdash \lambda x . e:(x: \tau \rightarrow \phi)} \forall-\mathrm{I} \\
& \frac{\Gamma \vdash e_{x}: \tau \quad \Gamma \vdash e:(x: \tau \rightarrow \phi)}{\Gamma \vdash e e_{x}: \phi\left[x / e_{x}\right]} \forall \text { - } \\
& \frac{\Gamma \vdash \mathrm{fst} e: \tau \quad \Gamma, x: \tau \vdash \text { snd } e: \phi}{\Gamma \vdash e:(x:: \tau, \phi[x / \mathrm{fst} e])} \exists-\mathrm{I} \quad \begin{array}{r}
\text { Г } e:\left(x:: \tau, \phi_{x}\right) \quad \Gamma, x: \tau, y: \phi_{x} \vdash e^{\prime}: \phi \\
\Gamma \vdash \operatorname{case} e \text { of }\left\{(x, y) \rightarrow e^{\prime}\right\}: \phi \\
\mathrm{E}
\end{array}
\end{aligned}
$$

Fig. 5. Natural deduction rules for refinement types. With [fst|snd] $e \equiv \operatorname{case} e$ of $\left\{\left(x_{1}, x_{2}\right) \rightarrow\left[x_{1} \mid x_{2}\right]\right\}$.

```
lenAppend :: xs:_ -> ys:_ -> {len (xs ++ ys) = len xs + len ys}
lenAppend [] _ = ()
lenAppend (x:xs) ys = lenAppend xs ys
```

Induction on Natural Numbers Finally, we specify and verify induction on natural numbers:

$$
\phi_{i n d} \equiv(p 0 \wedge(\forall n \cdot p(n-1) \Rightarrow p n) \Rightarrow \forall n \cdot p n)
$$

The proof proceeds by induction (e.g. case splitting). In the base case, $n==0$, the proof calls the left conjunct, which contains a proof of the base case. Otherwise, $0<n$, and the proof applies the induction hypothesis to the right conjunct instantiated at $n-1$.

```
ind p (p0, pn) 0 = p0
ind p (p0, pn) n = pn n (ind p (p0, pn) ( n-1))
```

### 3.4 Consequences

To summarize, we use the propositions-as-types principle to make two important contributions. First, we show that natural deduction reasoning can smoothly co-exist with SMT-based verification to automate the decidable, quantifier-free portions of the proof.

Second, we show for the first time how natural deduction proofs can be encoded in refinement type systems like Liquid Haskell and we expect this encoding to extend, in a straightforward manner to other SMT-based deductive verifiers (e.g. Dafny and $\mathrm{F}^{*}$ ). This encoding shows that refinement type systems are expressive enough to encode any intuitionistic natural deduction proof, gives a guideline for encoding proofs with nested quantifiers, and provides a pleasant implementation of natural deduction that is pedagogically useful.

## 4 REFINEMENT REFLECTION: $\lambda^{R}$

Refinement reflection encodes recursive functions in the quantifier-free, SMT logic and it is formalized in three steps. First, we develop a core calculus $\lambda^{R}$ with an undecidable type system based

$$
\begin{aligned}
& \text { Ops } \odot::==\mid< \\
& \text { Consts } c::=\wedge|!| \odot \mid+,-, \ldots \\
& \mid \text { True | False | } 0,-1,1, \ldots \\
& \text { Vals } w::=c|\lambda x . e| D \bar{w} \\
& \text { Exprs } e::=w|x| e e \\
& \mid \text { case } x=e \text { of }\{D \bar{x} \rightarrow e\} \\
& \text { Binds } b::=e \mid \text { let rec } x: \tau=b \text { in } b \\
& \text { Progs } p::=b \mid \text { reflect } x: \tau=e \text { in } p \\
& \text { Bas. Types } B:=\text { Int | Bool | T } \\
& \text { Ref. Types } \tau::=\left\{v: B^{[\Downarrow] ~} \mid e\right\} \mid x: \tau_{x} \rightarrow \tau
\end{aligned}
$$

Fig. 6. (Left) Syntax of $\lambda^{R}$ : Denotational Typing. (Right) Syntax of $\lambda^{S}$ : Algorithmic Typing.
on denotational semantics and prove it sound. Next, in $\S 5$ we define a language $\lambda^{S}$ that soundly approximates $\lambda^{R}$ while enabling decidable, SMT-based type checking. Finally, in § 6 we develop a complete proof search algorithm to automate equational reasoning.

### 4.1 Syntax

Figure 6 summarizes the syntax of $\lambda^{R}$, which is essentially the calculus $\lambda^{U}$ [56] with explicit recursion and a special reflect binding to denote terms that are reflected into the refinement logic. The elements of $\lambda^{R}$ are constants, values, expressions, binders, and programs.
Constants The constants of $\lambda^{R}$ include primitive relations $\odot$, here, the set $\{=,<\}$. Moreover, they include the booleans True, False, integers $-1,0,1$, etc., and logical operators $\wedge$, !, etc..
Data Constructors Data constructors are special constants. For example, the data type [Int], which represents finite lists of integers, has two data constructors: [] (nil) and : (cons).
Values \& Expressions The values of $\lambda^{R}$ include constants, $\lambda$-abstractions $\lambda x$.e, and fully applied data constructors $D$ that wrap values. The expressions of $\lambda^{R}$ include values, variables $x$, applications $e e$, and case expressions.
Binders \& Programs A binder $b$ is a series of possibly recursive let definitions, followed by an expression. A program $p$ is a series of reflect definitions, each of which names a function that is reflected into the refinement logic, followed by a binder. The stratification of programs via binders is required so that arbitrary recursive definitions are allowed in the program but cannot be inserted into the logic via refinements or reflection. (We can allow non-recursive let binders in expressions $e$, but omit them for simplicity.)

### 4.2 Operational Semantics

We define $\hookrightarrow$ to be the small step, call-by-name $\beta$-reduction semantics for $\lambda^{R}$. We evaluate reflected terms as recursive let bindings, with termination constraints imposed by the type system:

$$
\text { reflect } x: \tau=e \text { in } p \hookrightarrow \text { let } \operatorname{rec} x: \tau=e \text { in } p
$$

We define $\hookrightarrow^{\star}$ to be the reflexive, transitive closure of $\hookrightarrow$. Moreover, we define $\approx_{\beta}$ to be the reflexive, symmetric, and transitive closure of $\hookrightarrow$.
Constants Application of a constant requires the argument be reduced to a value; in a single step, the expression is reduced to the output of the primitive constant operation, i.e. $c v \hookrightarrow \delta(c, v)$. For
example, consider $=$, the primitive equality operator on integers. We have $\delta(=, n) \doteq={ }_{n}$ where $\delta\left(={ }_{n}, m\right)$ equals True iff $m$ is the same as $n$.
Equality We assume that the equality operator is defined for all values, and, for functions, is defined as extensional equality. That is, for all $f$ and $f^{\prime},\left(f=f^{\prime}\right) \hookrightarrow$ True iff $\forall v . f v \approx_{\beta} f^{\prime} v$. We assume source terms only contain implementable equalities over non-function types; while function extensional equality only appears in refinements.

### 4.3 Types

$\lambda^{R}$ types include basic types, which are refined with predicates, and dependent function types. Basic types $B$ comprise integers, booleans, and a family of data-types $T$ (representing lists, trees etc.). For example, the data type [Int] represents lists of integers. We refine basic types with predicates (boolean-valued expressions $e$ ) to obtain basic refinement types $\{v: B \mid e\}$. We use $\Downarrow$ to mark provably terminating computations and use refinements to ensure that if $e:\left\{v: B^{\Downarrow} \mid e^{\prime}\right\}$, then $e$ terminates. As discussed by Vazou et al. [56] termination labels are checked using refinement types and are used to ensure that refinements cannot diverge as required for soundness of type checking under lazy evaluation. Termination checking is crucial for this work, as combined with checks for exhaustive definitions (§ 2.1), it ensures totality (well-formedness) of expressions as required by propositions-as-types (§3) and termination of PLE (§ 6). Finally, we have dependent function types $x: \tau_{x} \rightarrow \tau$ where the input $x$ has the type $\tau_{x}$ and the output $\tau$ may refer to the input binder $x$. We write $B$ to abbreviate $\{v: B \mid$ True $\}$ and $\tau_{x} \rightarrow \tau$ to abbreviate $x: \tau_{x} \rightarrow \tau$, if $x$ does not appear in $\tau$.
Denotations Each type $\tau$ denotes a set of expressions $\llbracket \tau \rrbracket$, that is defined via the operational semantics [27]. Let shape $(\tau)$ be the type we get if we erase all refinements from $\tau$ and $e: \operatorname{shape}(\tau)$ be the standard typing relation for the typed lambda calculus. Then, we define the denotation of types as:

$$
\begin{aligned}
\llbracket\{x: B \mid r\} \rrbracket & \doteq\left\{e \mid e: B, \text { if } e \hookrightarrow^{\star} w \text { then } r[x / w] \hookrightarrow^{\star} \text { True }\right\} \\
\llbracket\left\{x: B^{\Downarrow} \mid r\right\} \rrbracket & \doteq \llbracket\{x: B \mid r\} \rrbracket \cap\left\{e \mid \exists w . e \hookrightarrow^{\star} w\right\} \\
\llbracket x: \tau_{x} \rightarrow \tau \rrbracket & \doteq\left\{e \mid e: \operatorname{shape}\left(\tau_{x} \rightarrow \tau\right), \forall e_{x} \in \llbracket \tau_{x} \rrbracket .\left(e e_{x}\right) \in \llbracket \tau\left[x / e_{x}\right] \rrbracket\right\}
\end{aligned}
$$

Constants For each constant $c$ we define its type $\operatorname{prim}(c)$ such that $c \in \llbracket \operatorname{prim}(c) \rrbracket$. For example,

$$
\begin{aligned}
& \operatorname{prim}(3) \doteq\left\{v: \text { Int }^{\Downarrow} \mid v=3\right\} \\
& \operatorname{prim}(+) \doteq \mathrm{x}\left(\text { Int }^{\Downarrow} \rightarrow \mathrm{y}: \text { Int }^{\Downarrow} \rightarrow\left\{v: \text { Int }^{\Downarrow} \mid v=x+y\right\}\right. \\
& \operatorname{prim}(\leq) \doteq \mathrm{X}: \text { Int }^{\Downarrow} \rightarrow \mathrm{y}: \text { Int }^{\Downarrow} \rightarrow\left\{v: \text { Bool }^{\Downarrow} \mid v \Leftrightarrow x \leq y\right\}
\end{aligned}
$$

### 4.4 Refinement Reflection

Reflection strengthens function output types with a refinement that reflects the definition of the function in the logic. We do this by treating each reflect-binder (reflect $f: \tau=e$ in $p$ ) as a let rec-binder (let rec $f: \operatorname{Reflect}(\tau, e)=e$ in $p$ ) during type checking (rule T-Refl in Figure 7).
Reflection We write $\operatorname{Reflect}(\tau, e)$ for the reflection of the term $e$ into the type $\tau$, defined as

$$
\begin{array}{ll}
\operatorname{Reflect}\left(\left\{v: B^{\Downarrow} \mid r\right\}, e\right) & \doteq\left\{v: B^{\Downarrow} \mid r \wedge v=e\right\} \\
\operatorname{Reflect}\left(x: \tau_{x} \rightarrow \tau, \lambda x . e\right) & \doteq x: \tau_{x} \rightarrow \operatorname{Reflect}(\tau, e)
\end{array}
$$

As an example, recall from $\S 2$ that the reflect fib strengthens the type of fib with the refinement fibP. That is, let the user specified type of fib be $t_{f i b}$ and the its definition be definition $\lambda n . e_{f i b}$.

$$
\begin{aligned}
& t_{\mathrm{fib}} \doteq\left\{v: \text { Int }{ }^{\Downarrow} \mid 0 \leq v\right\} \rightarrow\left\{v: \text { Int }^{\Downarrow} \mid 0 \leq v\right\} \\
& e_{\mathrm{fib}} \doteq \text { case } x=n \leq 1 \text { of }\{\text { True } \rightarrow n ; \text { False } \rightarrow \text { fib }(n-1)+\text { fib }(n-2)\}
\end{aligned}
$$

Then, the reflected type of fib will be:

$$
\operatorname{Reflect}\left(t_{\mathrm{fib}}, e_{\mathrm{fib}}\right)=n:\left\{v: \operatorname{Int}^{\Downarrow} \mid 0 \leq v\right\} \rightarrow\left\{v: \operatorname{Int}^{\Downarrow} \mid 0 \leq v \wedge v=e_{\mathrm{fib}}\right\}
$$

Termination Checking We defined $\operatorname{Reflect}(\cdot, \cdot)$ to be a partial function that only reflects provably terminating expressions, i.e. expressions whose result type is marked with $\downarrow$. If a non-provably terminating function is reflected in an $\lambda^{R}$ expression then type checking will fail (with a reflection type error in the implementation). This restriction is crucial for soundness, as diverging expressions can lead to inconsistencies. For example, reflecting the diverging $f x=1+f x$ into the logic leads to an inconsistent system that is able to prove $0=1$.
Automatic Reflection Reflection of $\lambda^{R}$ expressions into the refinements happens automatically by the type system, not manually by the user. The user simply annotates a function $f$ as reflect $f$. Then, the rule T-Refl in Figure 7 is used to type check the reflected function by strengthening $f$ 's result via Reflect $(\cdot, \cdot)$. Finally, the rule T-Let is used to check that the automatically strengthened type of $f$ satisfies $f$ 's implementation.

### 4.5 Typing Rules

Next, we present the type-checking rules of $\lambda^{R}$, as found in Figure 7.
Environments and Closing Substitutions A type environment $\Gamma$ is a sequence of type bindings $x_{1}: \tau_{1}, \ldots, x_{n}: \tau_{n}$. An environment denotes a set of closing substitutions $\theta$ which are sequences of expression bindings: $x_{1} \mapsto e_{1}, \ldots, x_{n} \mapsto e_{n}$ such that:

$$
\llbracket \Gamma \rrbracket \doteq\{\theta \mid \forall x: \tau \in \Gamma \cdot \theta(x) \in \llbracket \theta \cdot \tau \rrbracket\}
$$

where $\theta \cdot \tau$ applies a substitution to a type (and likewise $\theta \cdot p$, to a program).
A reflection environment $R$ is a sequence that binds the names of the reflected functions with their definitions $f_{1} \mapsto e_{1}, \ldots, f_{n} \mapsto e_{n}$. A reflection environment respects a type environment when all reflected functions satisfy their types:

$$
\Gamma \mid=R \doteq \forall(f \mapsto e) \in R . \exists \tau .(f: \tau) \in \Gamma \wedge(\Gamma ; R \vdash e: \tau)
$$

Typing A judgment $\Gamma ; R \vdash p: \tau$ states that the program $p$ has the type $\tau$ in the type environment $\Gamma$ and the reflection environment $R$. That is, when the free variables in $p$ are bound to expressions described by $\Gamma$, the program $p$ will evaluate to a value described by $\tau$.
Rules All but two of the rules are standard [27,56] except for the addition of the reflection environment $R$ at each rule. First, rule T-Refl is used to extend the reflection environment with the binding of the function name with its definition $(f \mapsto e)$ and moreover to strengthen the type of each reflected binder with its definition, as described previously in § 4.4. Second, rule T-Exact strengthens the expression with a singleton type equating the value and the expression (i.e. reflecting the expression in the type). This is a generalization of the "selfification" rules from $[27,39]$ and is required to equate the reflected functions with their definitions. For example, the application fib 1 is typed as $\left\{v:\right.$ Int ${ }^{\Downarrow} \mid$ fibP $1 \wedge v=$ fib 1$\}$ where the first conjunct comes from the (reflection-strengthened) output refinement of fib (§ 2 ) and the second comes from rule T-ExACT.

## Typing

\end{aligned}
$$

## Well Formedness

$$
\frac{\Gamma, v: B ; \emptyset \vdash e: \text { Bool } \Downarrow}{\Gamma \vdash\{v: B \mid e\}} \text { WF-BASE } \quad \frac{\Gamma \vdash \tau_{x} \Gamma, x: \tau_{x} \vdash \tau}{\Gamma \vdash x: \tau_{x} \rightarrow \tau} \text { WF-FUN }
$$

## Subtyping

$$
\begin{gathered}
\forall \theta \in \llbracket \Gamma \rrbracket \cdot \llbracket \theta \cdot\left\{v: B \mid e_{1}\right\} \rrbracket \subseteq \llbracket \theta \cdot\left\{v: B \mid e_{2}\right\} \rrbracket \\
\Gamma ; R \vdash\left\{v: B \mid e_{1}\right\} \leq\left\{v: B \mid e_{2}\right\} \\
\frac{\Gamma ; \text {-BASE- } \lambda^{R}}{\Gamma \vdash \tau_{x}^{\prime} \leq \tau_{x} \quad \Gamma, x: \tau_{x}^{\prime} ; R \vdash \tau \leq \tau^{\prime}} \\
\Gamma ; R \vdash x: \tau_{x} \rightarrow \tau \leq x: \tau_{x}^{\prime} \rightarrow \tau^{\prime} \\
\text {-FuN }
\end{gathered}
$$

Fig. 7. Typing of $\lambda^{R}$.
Well-formedness A judgment $\Gamma \vdash \tau$ states that the refinement type $\tau$ is well-formed in the environment $\Gamma$. Following Vazou et al. [56], $\tau$ is well-formed if all the refinements in $\tau$ are Booltyped, provably terminating expressions in $\Gamma$.
Subtyping A judgment $\Gamma ; R \vdash \tau_{1} \leq \tau_{2}$ states that the type $\tau_{1}$ is a subtype of $\tau_{2}$ in the environments $\Gamma$ and $R$. Informally, $\tau_{1}$ is a subtype of $\tau_{2}$ if, when the free variables of $\tau_{1}$ and $\tau_{2}$ are bound to expressions described by $\Gamma$, the denotation of $\tau_{1}$ is contained in the denotation of $\tau_{2}$. Subtyping of basic types reduces to denotational containment checking, shown in rule $\leq$-BASE- $\lambda^{R}$. That is, $\tau_{1}$ is a subtype of $\tau_{2}$ under $\Gamma$ if for any closing substitution $\theta$ in $\llbracket \Gamma \rrbracket, \llbracket \theta \cdot \tau_{1} \rrbracket$ is contained in $\llbracket \theta \cdot \tau_{2} \rrbracket$.
Soundness We prove that typing implies denotational inclusion and evaluation preserves typing.
Theorem 4.1. [Soundness of $\lambda^{R}$ ]

- Denotations If $\Gamma ; R \vdash p: \tau$, then $\forall \theta \in \llbracket \Gamma \rrbracket . \theta \cdot p \in \llbracket \theta \cdot \tau \rrbracket$.
- Preservation If $\emptyset ; \emptyset \vdash p: \tau$ and $p \hookrightarrow{ }^{\star} w$, then $\emptyset ; \emptyset \vdash w: \tau$.

The proofs can be found in [58]. Theorem 4.1 lets us prove that if $\phi$ is a $\lambda^{R}$ type interpreted as a proposition (using the mapping of Figure 3) and if there exists a $p$ so that $\emptyset ; \emptyset \vdash p: \phi$, the $\phi$ is valid. For example, in § 2 we verified that the term fibUp proves $n$ : Nat $\rightarrow\{$ fib $n \leq \operatorname{fib}(n+1)\}$. Via soundness of $\lambda^{R}$, we get that for each valid input n , the result refinement is valid.

$$
\forall n .0 \leq n \hookrightarrow^{\star} \text { True } \Rightarrow \text { fib } n \leq \operatorname{fib}(n+1) \hookrightarrow^{\star} \text { True }
$$

## 5 ALGORITHMIC CHECKING: $\lambda^{S}$

$\lambda^{S}$ is a first order approximation of $\lambda^{R}$ where higher-order features are approximated with uninterpreted functions and the undecidable type subsumption rule $\leq$-BASE- $\lambda^{R}$ is replaced with a decidable one (i.e., $\leq$-BASE-PLE), yielding an sound and decidable SMT-based algorithmic type system. Figure 6 summarizes the syntax of $\lambda^{S}$, the sorted (SMT-) decidable logic of quantifier-free equality, uninterpreted functions and linear arithmetic (QF-EUFLIA) [5, 36]. The terms of $\lambda^{S}$ include integers $n$, booleans $b$, variables $x$, data constructors $D$ (encoded as constants), fully applied unary $\oplus_{1}$ and binary $\bowtie$ operators, and application $x \bar{p}$ of an uninterpreted function $x$. The sorts of $\lambda^{S}$ include the built-in Int and Bool to represent integers and booleans and the uninterpreted $U$ to represent data types. The interpreted functions of $\lambda^{S}$, e.g. the logical constants $=$ and $<$, have the function sort $s \rightarrow s$. Other functional values in $\lambda^{R}$, e.g. reflected $\lambda^{R}$ functions and $\lambda$-expressions, are represented as first-order values with the uninterpreted sort Fun ss.

### 5.1 Transforming $\lambda^{R}$ into $\lambda^{S}$

The judgment $\Gamma \vdash e \rightsquigarrow p$ states that a $\lambda^{R}$ term $e$ is transformed, under an environment $\Gamma$, into a $\lambda^{S}$ term $p$. If $\Gamma \vdash e \rightsquigarrow p$ and $\Gamma$ is clear from the context we write $\lfloor e\rfloor$ and $\lceil p\rceil$ to denote the translation from $\lambda^{R}$ to $\lambda^{S}$ and back. Most of the transformation rules are identity and can be found in [58]. Here we discuss the non-identity ones.
Embedding Types We embed $\lambda^{R}$ types into $\lambda^{S}$ sorts as:

$$
\begin{array}{lll}
\lfloor\text { Int }\rfloor \doteq \text { Int } & \lfloor T\rfloor \doteq U & \left\lfloor\left\{v: B^{[\Downarrow\rfloor} \mid e\right\}\right\rfloor \\
\lfloor\text { Bool }\rfloor & \doteq \text { Bool } & \\
& \left\lfloor x: \tau_{x} \rightarrow \tau\right\rfloor & \doteq \text { Fun }\left\lfloor\tau_{x}\right\rfloor\lfloor\tau\rfloor
\end{array}
$$

Embedding Constants Elements shared on both $\lambda^{R}$ and $\lambda^{S}$ translate to themselves. These elements include booleans, integers, variables, binary and unary operators. SMT solvers do not support currying, and so in $\lambda^{S}$, all function symbols must be fully applied. Thus, we assume that all applications to primitive constants and data constructors are fully applied, e.g. by converting source terms like ( +1 ) to ( $\backslash z \rightarrow z+1$ ).
Embedding Functions As $\lambda^{S}$ is first-order, we embed $\lambda s$ using the uninterpreted function lam.

$$
\frac{\Gamma, x: \tau_{x} \vdash e \rightsquigarrow p \quad \Gamma ; \emptyset \vdash(\lambda x . e):\left(x: \tau_{x} \rightarrow \tau\right)}{\Gamma \vdash \lambda x . e \rightsquigarrow \operatorname{lam}_{\lfloor\tau\rfloor}^{\left\lfloor\tau_{x}\right\rfloor} x p}
$$

The term $\lambda x . e$ of type $\tau_{x} \rightarrow \tau$ is transformed to $\operatorname{lam}_{s}^{s_{x}} x p$ of sort Fun $s_{x} s$, where $s_{x}$ and $s$ are respectively $\left\lfloor\tau_{x}\right\rfloor$ and $\lfloor\tau\rfloor$, $1 \mathrm{am}_{s}^{s_{x}}$ is a special uninterpreted function of sort $s_{x} \rightarrow s \rightarrow$ Fun $s_{x} s$, and $x$ of sort $s_{x}$ and $p$ of sort $s$ are the embeddings of the binder and body, respectively. As lam is an SMT-function, it does not create a binding for $x$. Instead, $x$ is renamed to a fresh SMT name.
Embedding Applications We use defunctionalization [40] to embed applications.

$$
\frac{\Gamma \vdash e_{x} \rightsquigarrow p_{x} \quad \Gamma \vdash e \rightsquigarrow p \quad \Gamma ; \emptyset \vdash e: \tau_{x} \rightarrow \tau}{\Gamma \vdash e e_{x} \rightsquigarrow \operatorname{app}_{\lfloor\tau\rfloor}^{\left\lfloor\tau_{x}\right\rfloor} p p_{x}}
$$

The term $e e_{x}$, where $e$ and $e_{x}$ have types $\tau_{x} \rightarrow \tau$ and $\tau_{x}$, is transformed to app $s_{s}^{s_{x}} p p_{x}: s$ where $s$ and $s_{x}$ are $\lfloor\tau\rfloor$ and $\left\lfloor\tau_{x}\right\rfloor$, the app $s_{s}^{s_{x}}$ is a special uninterpreted function of sort Fun $s_{x} s \rightarrow s_{x} \rightarrow s$, and $p$ and $p_{x}$ are the respective translations of $e$ and $e_{x}$.
Embedding Data Types We embed data constructors to a predefined $\lambda^{S}$ constant $s_{D}$ of sort $\lfloor\operatorname{prim}(D)\rfloor: \Gamma \vdash D \rightsquigarrow \mathrm{~s}_{D}$. For each datatype, we create reflected functions that check the top-level constructor and select their individual fields. For example, for lists, we create the functions

```
isNil [] = True isCons (x:xs) = True sel1 (x:xs) = x
isNil (x:xs) = False isCons [] = False sel2 (x:xs) = xs
```

The above selectors can be modeled precisely in the refinement logic via SMT support for ADTs [36]. To generalize, let $D_{i}$ be a data constructor such that $\operatorname{prim}\left(D_{i}\right) \doteq \tau_{i, 1} \rightarrow \cdots \rightarrow \tau_{i, n} \rightarrow \tau$. Then check is $_{D_{i}}$ has the sort Fun $\lfloor\tau\rfloor$ Bool and select $\operatorname{sel}_{D_{i, j}}$ has the sort Fun $\lfloor\tau\rfloor\left\lfloor\tau_{i, j}\right\rfloor$.
Embedding Case Expressions We translate case-expressions of $\lambda^{R}$ into nested if terms in $\lambda^{S}$, by using the check functions in the guards and the select functions for the binders of each case.

$$
\frac{\Gamma \vdash e \rightsquigarrow p \quad \Gamma \vdash e_{i}\left[\overline{y_{i}} / \overline{\operatorname{sel}_{D_{i}} x}\right][x / e] \rightsquigarrow p_{i}}{\Gamma \vdash \text { case } x=e \text { of }\left\{D_{i} \overline{y_{i}} \rightarrow e_{i}\right\} \rightsquigarrow \text { if app is } D_{D_{1}} p \text { then } p_{1} \text { else } \ldots \text { else } p_{n}}
$$

The above translation yields the reflected definition for append ( ++ ) from (§ 2.5).
Semantic Preservation The translation preserves the semantics of the expressions. Informally, if $\Gamma \vdash e \rightsquigarrow p$, then for every substitution $\theta$ and every logical model $\sigma$ that respects the environment $\Gamma$ if $\theta \cdot e \hookrightarrow^{\star} v$ then $\sigma \vDash p=\lfloor v\rfloor$.

### 5.2 Algorithmic Type Checking

We make the type checking from Figure 7 algorithmic by checking subtyping via our novel, SMTbased Proof by Logical Evaluation(PLE). Next, we formalize how PLE makes checking algorithmic and in § 6 we describe the PLE procedure in detail.
Verification Conditions Recall that in $\S 5.1$ we defined $\lfloor\cdot\rfloor$ as the translation from $\lambda^{R}$ to $\lambda^{S}$. Informally, the implication or verification condition (VC) $\lfloor\Gamma\rfloor \Rightarrow p_{1} \Rightarrow p_{2}$ is valid only if the set of values described by $p_{1}$ is subsumed by the set of values described by $p_{2}$ under the assumptions of $\Gamma$. $\Gamma$ is embedded into logic by conjoining the refinements of terminating binders [56]:

Validity Checking Instead of directly using the VCs to check validity of programs, we use the procedure PLE that strengthens the assumption environment $\lfloor\Gamma\rfloor$ with equational properties. Concretely, given a reflection environment $R$, type environment $\Gamma$, and expression $e$, the procedure $\operatorname{PLE}(\lfloor R\rfloor,\lfloor\Gamma\rfloor,\lfloor e\rfloor)$ - we will define $\lfloor R\rfloor$ in $\S 6.1$ - returns true only when the expression $e$ evaluates to True under the reflection and type environments $R$ and $\Gamma$.
Subtyping via VC Validity Checking We make subtyping, and hence, typing decidable, by replacing the denotational base subtyping rule $\leq-$ BASE- $\lambda^{R}$ with the conservative, algorithmic version $\leq$-BASE-PLE that uses PLE to check the validity of the subtyping.

$$
\frac{\operatorname{PLE}\left(\lfloor R\rfloor,\left\lfloor\Gamma, v:\left\{v: B^{\Downarrow} \mid e_{1}\right\}\right\rfloor,\left\lfloor e_{2}\right\rfloor\right)}{\Gamma ; R \vdash_{P L E}\left\{v: B \mid e_{1}\right\} \leq\left\{v: B \mid e_{2}\right\}} \leq \text {-BASE-PLE }
$$

This typing rule is sound as functions reflected in $R$ always respect the typing environment $\Gamma$ (by construction) and because PLE is sound (Theorem 6.2).

$$
\begin{array}{rrl}
\text { Terms } & p, t, b & ::=\lambda^{S} \text { if-free terms from Figure } 6 \\
\text { Functions } & F & ::=\lambda \bar{x} \cdot\langle\overline{p \Rightarrow b}\rangle \\
\text { Definitional Environment } & \Psi & ::=\emptyset \mid f \mapsto F, \Psi \\
\text { Logical Environment } & \Phi & ::=\emptyset \mid p, \Phi
\end{array}
$$

Fig. 8. Syntax of Predicates, Terms and Reflected Functions.

Lemma 5.1. If $\Gamma ; R \vdash_{P L E}\left\{v: B \mid e_{1}\right\} \leq\left\{v: B \mid e_{2}\right\}$ then $\Gamma ; R \vdash\left\{v: B \mid e_{1}\right\} \leq\left\{v: B \mid e_{2}\right\}$.
Soundness of $\lambda^{S}$ We write $\Gamma ; R \vdash_{\text {PLE }} e: \tau$ for the judgments that can be derived by the algorithmic subtyping rule $\leq$-BASE-PLE (instead of $\leq$-BASE- $\lambda^{R}$.) Lemma 5.1 implies the soundness of $\lambda^{S}$.

Theorem 5.2 (Soundness of $\lambda^{S}$ ). If $\Gamma ; R \vdash$ ple $e: \tau$, then $\Gamma ; R \vdash e: \tau$.

## 6 COMPLETE VERIFICATION: PROOF BY LOGICAL EVALUATION

Next, we formalize our Proof By Logical Evaluation algorithm PLE and show that it is sound (§ 6.1), that it is complete with respect to equational proofs (§ 6.2), and that it terminates (§ 6.3).

### 6.1 Algorithm

Figure 8 describes the input environments for PLE. The logical environment $\Phi$ contains a set of hypotheses $p$, described in Figure 6. The definitional environment $\Psi$ maps function symbols $f$ to their definitions $\lambda \bar{x} .\langle\overline{p \Rightarrow b}\rangle$, written as $\lambda$-abstractions over guarded bodies. Moreover, the body $b$ and the guard $p$ contain neither $\lambda$ nor if. These restrictions do not impact expressiveness: $\lambda$ s can be named and reflected, and if-expressions can be pulled out into top-level guards using $\operatorname{DeIf}(\cdot)$, defined in [58]. A definitional environment $\Psi$ can be constructed from $R$ as

$$
\lfloor R\rfloor \doteq\{f \mapsto \lambda \bar{x} \cdot \operatorname{DeIf}(\lfloor e\rfloor) \mid(f \mapsto \lambda \bar{x} \cdot e) \in R\}
$$

Notation We write $f\left(t_{1}, \ldots, t_{n}\right)<\Phi$ if the $\lambda^{S}$ term (app $\left.\ldots\left(\operatorname{app} f t_{1}\right) \ldots t_{n}\right)$ is a syntactic subterm of some $t \in \Phi$. We abuse notation to write $f(\bar{t})<t^{\prime}$ for $f(\bar{t})<\left\{t^{\prime}\right\}$. We write $\operatorname{SmtValid}(\Phi, p)$ for SMT validity of the implication $\Phi \Rightarrow p$.
Instantiation \& Unfolding A term $q$ is a $(\Psi, \Phi)$-instance if there exists $f(\bar{t})<\Phi$ such that:

- $\Psi(f) \equiv \lambda \bar{x} .\left\langle\overline{p_{i} \Rightarrow b_{i}}\right\rangle$,
- $\operatorname{SmtValid}\left(\Phi, p_{i}[\bar{t} / \bar{x}]\right)$, and
- $q \equiv\left(f(\bar{x})=b_{i}\right)[\bar{t} / \bar{x}]$.

A set of terms $Q$ is a $(\Psi, \Phi)$-instance if every $q \in Q$ is an $(\Psi, \Phi)$-instance. The unfolding of $\Psi, \Phi$ is the (finite) set of all ( $\Psi, \Phi$ )-instances. Procedure Unfold $(\Psi, \Phi)$ shown in Figure 9 computes and returns the conjunction of $\Phi$ and the unfolding of $\Psi, \Phi$. The following properties relate ( $\Psi, \Phi$ )-instances to the semantics of $\lambda^{R}$ and SMT validity. Let $R[e]$ denote the evaluation of $e$ under the reflection environment $R$, i.e. $\emptyset[e] \doteq e$ and $\left(R, f: e_{f}\right)[e] \doteq R\left[\right.$ let rec $f=e_{f}$ in $\left.e\right]$.

Lemma 6.1. For every $\Gamma \mid=R$ and $\theta \in(\Gamma\rceil$,

- Sat-Inst If $\lfloor e\rfloor$ is $a(\lfloor R\rfloor,\lfloor\Gamma\rfloor)$-instance, then $\theta \cdot R[e] \hookrightarrow^{\star}$ True.
- SMT-Approx If SmtValid $(\lfloor\Gamma\rfloor,\lfloor e\rfloor)$, then $\theta \cdot R[e] \hookrightarrow^{\star}$ True.
- SMT-Inst If $q$ is $a(\lfloor R\rfloor,\lfloor\Gamma\rfloor)$-instance and $\operatorname{SmtValid}(\lfloor\Gamma\rfloor \cup\{q\},\lfloor e\rfloor)$, then $\theta \cdot R[e] \hookrightarrow{ }^{\star}$ True.

The Algorithm Figure 9 shows our proof search algorithm $\operatorname{PLE}(\Psi, \Phi, p)$ which takes as input a set of reflected definitions $\Psi$, an hypothesis $\Phi$, and a goal $p$. The PLE procedure recursively unfolds

Fig. 9. Algorithm PLE: Proof by Logical Evaluation.
function application terms by invoking Unfold until either the goal can be proved using the unfolded instances (in which case the search returns true) or no new instances are generated by the unfolding (in which case the search returns false).
Soundness First, we prove the soundness of PLE.
Theorem 6.2 (Soundness). If $\operatorname{PLE}(\lfloor R\rfloor,\lfloor\Gamma\rfloor,\lfloor e\rfloor)$ then $\forall \theta \in(\Gamma\rceil), \theta \cdot R[e] \hookrightarrow^{\star}$ True.
We prove Theorem 6.2 using the Lemma 6.1 that relates instantiation, SMT validity, and the exact semantics. Intuitively, PLE is sound as it reasons about a finite set of instances by conservatively treating all function applications as uninterpreted [36].

### 6.2 Completeness

Next, we show that our proof search is complete with respect to equational reasoning. We define a notion of equational proof $\Psi, \Phi \vdash t \rightarrow t^{\prime}$ and prove that if there exists such a proof, then $\operatorname{PLE}\left(\Psi, \Phi, t=t^{\prime}\right)$ is guaranteed to return true. To prove this theorem, we introduce the notion of bounded unfolding which corresponds to unfolding definitions $n$ times. We show that unfolding preserves congruences, and hence, that an equational proof exists iff the goal can be proved with some bounded unfolding. Thus, completeness follows by showing that the proof search procedure computes the limit (i.e. fixpoint) of the bounded unfolding. In § 6.3 we show that the fixpoint is computable: there exists an unfolding depth at which PLE reaches a fixpoint and hence terminates.
Bounded Unfolding For every $\Psi, \Phi$, and $0 \leq n$, the bounded unfolding of depth $n$ is defined by:

```
Unfold \({ }^{*}(\Psi, \Phi, 0) \quad \doteq \quad \Phi\)
Unfold \({ }^{*}(\Psi, \Phi, n+1) \doteq \Phi_{n} \cup \operatorname{Unfold}\left(\Psi, \Phi_{n}\right) \quad\) where \(\Phi_{n}=\operatorname{Unfold}{ }^{*}(\Psi, \Phi, n)\)
```

That is, the unfolding at depth $n$ essentially performs Unfold upto $n$ times. The bounded-unfoldings yield a monotonically non-decreasing sequence of formulas such that if two consecutive bounded unfoldings coincide, then all subsequent unfoldings are the same.

$$
\begin{gathered}
\frac{\Psi, \Phi \vdash t \rightarrow t}{} \mathrm{EQ}-\mathrm{Refl} \\
\Psi, \Phi \vdash t \rightarrow t^{\prime \prime} \quad \Phi^{\prime}=\operatorname{Unfold}\left(\Psi, \Phi \cup\left\{v=t^{\prime \prime}\right\}\right) \quad \operatorname{SmtValid}\left(\Phi^{\prime}, v=t^{\prime}\right) \\
\Psi, \Phi \vdash t \rightarrow t^{\prime} \\
\Psi, \Phi \vdash t_{1} \rightarrow t_{1}^{\prime} \quad \Psi, \Phi \vdash t_{2} \rightarrow t_{2}^{\prime} \quad \operatorname{SmtValid}\left(\Phi, t_{1}^{\prime} \bowtie t_{2}^{\prime}\right) \\
\Psi, \Phi \vdash t_{1} \bowtie t_{2}
\end{gathered} \text { EQ-Trans }
$$

Fig. 10. Equational Proofs: rules for equational reasoning.

Lemma 6.3 (Monotonicity). $\forall 0 \leq n$. Unfold* $(\Psi, \Phi, n) \subseteq \operatorname{Unfold}^{*}(\Psi, \Phi, n+1)$.
Lemma $6.4($ Fixpoint $) . ~ L e t ~ \Phi_{i} \doteq \operatorname{Unfold}^{*}(\Psi, \Phi, i)$. If $\Phi_{n}=\Phi_{n+1}$, then $\forall n<m . \Phi_{m}=\Phi_{n}$.
Uncovering Next, we prove that every function application term that is uncovered by unfolding to depth $n$ is congruent to a term in the $n$-depth unfolding.

Lemma 6.5 (Uncovering). Let $\Phi_{n} \equiv \operatorname{Unfold}^{*}\left(\Psi, \Phi \cup\{v=t\}\right.$, $n$ ). If $\operatorname{Smt} \operatorname{Valid}\left(\Phi_{n}, v=t^{\prime}\right)$, then for every $f\left(\overline{t^{\prime}}\right)<t^{\prime}$ there exists $f(\bar{t})<\Phi_{n}$ such that $\operatorname{SmtValid}\left(\Phi_{n}, t_{i}=t_{i}^{\prime}\right)$.

We prove the above lemma by induction on $n$ where the inductive step uses the following property of congruence closure, which itself is proved by induction on the structure of $t^{\prime}$ :

Lemma 6.6 (Congruence). If $\operatorname{Smt} \operatorname{Valid}\left(\Phi \cup\{v=t\}, v=t^{\prime}\right)$ and $v \notin \Phi, t, t^{\prime}$, then for every $f\left(\overline{t^{\prime}}\right) \prec t^{\prime}$ there exists $f(\bar{t}) \prec \Phi, t$ such that $\operatorname{SmtValid}\left(\Phi, t_{i}=t_{i}^{\prime}\right)$.

Unfolding Preserves Equational Links We use the uncovering Lemma 6.5 and congruence to show that every instantiation that is valid after $n$ steps is subsumed by the $n+1$ depth unfolding. That is, we show that every possible link in any equational chain can be proved equal to the source expression via bounded unfolding.

Lemma 6.7 (Link). IfSmtValid(Unfold $\left.{ }^{*}(\Psi, \Phi \cup\{v=t\}, n), v=t^{\prime}\right)$, then SmtValid(Unfold* $(\Psi, \Phi \cup$ $\left.\{v=t\}, n+1), \operatorname{Unfold}\left(\Psi, \Phi \cup\left\{v=t^{\prime}\right\}\right)\right)$.

Equational Proof Figure 10 formalizes our rules for equational reasoning. Intuitively, there is an equational proof that $t_{1} \bowtie t_{2}$ under $\Psi$, $\Phi$, written by the judgment $\Psi$, $\Phi \vdash t_{1} \bowtie t_{2}$, if by some sequence of repeated function unfoldings, we can prove that $t_{1}$ and $t_{2}$ are respectively equal to $t_{1}^{\prime}$ and $t_{2}^{\prime}$ such that, $\operatorname{Smt} \operatorname{Valid}\left(\Phi, t_{1}^{\prime} \bowtie t_{2}^{\prime}\right)$ holds. Our notion of equational proofs adapts the idea of type level computation used in TT-based proof assistants to the setting of SMT-based reasoning, via the directional unfolding judgment $\Psi, \Phi \vdash t \rightarrow t^{\prime}$. In the SMT-realm, the explicit notion of a normal or canonical form is converted to the implicit notion of the equivalence classes of the SMT solver's congruence closure procedure (post-unfolding).
Completeness of Bounded Unfolding We use the fact that unfolding preserves equational links to show that bounded unfolding is complete for equational proofs. That is, we prove by induction on the structure of the equational proof that whenever there is an equational proof of $t=t^{\prime}$, there exists some bounded unfolding that suffices to prove the equality.

Lemma 6.8. If $\Psi, \Phi \vdash t \rightarrow t^{\prime}$, then $\exists 0 \leq n$. SmtValid(Unfold* $\left.(\Psi, \Phi \cup\{v=t\}, n), v=t^{\prime}\right)$.

PLE is a Fixpoint of Bounded Unfolding We show that the proof search procedure PLE computes the least-fixpoint of the bounded unfolding and hence, returns true iff there exists some unfolding depth $n$ at which the goal can be proved.

Lemma 6.9 (Fixpoint). $\operatorname{PLE}\left(\Psi, \Phi, t=t^{\prime}\right)$ iff $\exists n$. SmtValid(Unfold $\left.{ }^{*}(\Psi, \Phi \cup\{v=t\}, n), v=t^{\prime}\right)$.
The proof follows by observing that $\operatorname{PLE}\left(\Psi, \Phi, t=t^{\prime}\right)$ computes the least-fixpoint of the sequence $\Phi_{i} \doteq$ Unfold* $(\Psi, \Phi, i)$. Specifically, we prove by induction on $i$ that at each invocation of loop ( $i, \Phi_{i}$ ) in Figure $9, \Phi_{i}$ is equal to $U_{\text {nfold }}{ }^{*}(\Psi, \Phi \cup\{v=t\}, i)$, which then yields the result.
Completeness of PLE Finally, we combine Lemmas 6.9 and 6.7 to show that PLE is complete, i.e. if there is an equational proof that $t \bowtie t^{\prime}$ under $\Psi, \Phi$, then $\operatorname{PLE}\left(\Psi, \Phi, t \bowtie t^{\prime}\right)$ returns true.

Theorem 6.10 (Completeness). If $\Psi, \Phi \vdash t \bowtie t^{\prime}$ then $\operatorname{PLE}\left(\Psi, \Phi, t \bowtie t^{\prime}\right)=$ true.

### 6.3 PLE Terminates

So far, we have shown that our proof search procedure PLE is both sound and complete. Both of these are easy to achieve simply by enumerating all possible instances and repeatedly querying the SMT solver. Such a monkeys-with-typewriters approach is rather impractical: it may never terminate. Fortunately, we show that in addition to being sound and complete with respect to equational proofs, if the hypotheses are transparent, then our proof search procedure always terminates. Next, we describe transparency and explain intuitively why PLE terminates. We then develop the formalism needed to prove the termination Theorem 6.16.
Transparency An environment $\Gamma$ is inconsistent if $\operatorname{SmtValid}(\lfloor\Gamma\rfloor, f a l s e)$. An environment $\Gamma$ is inhabited if there exists some $\theta \in\lceil\Gamma\rceil$. We say $\Gamma$ is transparent if it is either inhabited or inconsistent. As an example of a non-transparent $\Phi_{0}$ consider the predicate lenA xs $=1+$ lenB xs, where lenA and lenB are both identical definitions of the list length function. Clearly there is no $\theta$ that causes the above predicate to evaluate to true. At the same time, the SMT solver cannot (using the decidable, quantifier-free theories) prove a contradiction as that requires induction over xs. Thus, non-transparent environments are somewhat pathological and, in practice, we only invoke PLE on transparent environments. Either the environment is inconsistent, e.g. when doing a proof-bycontradiction, or e.g. when doing a proof-by-case-analysis we can easily find suitable concrete values via random [13] or SMT-guided generation [45].
Challenge: Connect Concrete and Logical Semantics As suggested by its name, the PLE algorithm aims to lift the notion of evaluation or computations into the level of the refinement logic. Thus, to prove termination, we must connect the two different notions of evaluation, the concrete (operational) semantics and the logical semantics being used by PLE. This connection is trickier than appears at first glance. In the concrete realm totality ensures that every reflected function $f$ will terminate when run on any individual value $v$. However, in the logical realm, we are working with infinite sets of values, compactly represented via logical constraints. In other words, the logical realm can be viewed (informally) as an abstract interpretation of the concrete semantics. We must carefully argue that despite the approximation introduced by the logical abstraction, the abstract interpretation will also terminate.
Solution: Universal Abstract Interpretation We make this termination argument in three steps. First, we formalize how PLE performs computation at the logical level via logical steps and logical traces. We show (Lemma 6.13) that the logical steps form a so-called universal (or must) abstraction of the concrete semantics $[14,18]$. Second, we show that if PLE diverges, it is because it creates a strictly increasing infinite chain, Unfold ${ }^{*}(\Psi, \Phi, 0) \subset \operatorname{Unfold}^{*}(\Psi, \Phi, 1) \ldots$ which corresponds to an infinite logical trace. Third, as the logical computation is a universal abstraction we use inhabitation to connect the two realms, i.e. to show that an infinite logical trace corresponds to an infinite
concrete trace. The impossibility of the latter must imply the impossibility of the former, i.e. PLE terminates. Next, we formalize the above to obtain Theorem 6.16.
Totality A function is total when its evaluation reduces to exactly one value. The totality of $R$ can and is checked by refinement types (§4). Hence, for brevity, in the sequel we implicitly assume that $R$ is total under $\Gamma$.

Definition 6.11 (Total). Let $b \equiv \lambda \bar{x} \cdot\langle\overline{\lfloor p\rfloor \Rightarrow\lfloor e\rfloor}\rangle . b$ is total under $\Gamma$ and $R$, if forall $\theta \in(\Gamma\rangle$ :
(1) if $\theta \cdot R\left[p_{i}\right] \hookrightarrow^{\star}$ True, then $\exists v \cdot \theta \cdot R\left[e_{i}\right] \hookrightarrow^{\star} v$,
(2) if $\theta \cdot R\left[p_{i}\right] \hookrightarrow^{\star}$ True and $\theta \cdot \Psi\left[p_{j}\right] \hookrightarrow^{\star}$ True, then $i=j$, and
(3) there exists an $i$ so that $\theta \cdot R\left[p_{i}\right] \hookrightarrow^{\star}$ True.
$R$ is total under $\Gamma$, if every $b \in\lfloor R\rfloor$ is total under $\Gamma$ and $R$.
Subterm Evaluation As the reflected functions are total, the Church-Rosser theorem implies that evaluation order is not important. To prove termination, we require an evaluation strategy, e.g. CBV, in which if a reflected function's guard is satisfied, then the evaluation of the corresponding function body requires evaluating every subterm inside the body. As DeIf $(\cdot)$ hoists if-expressions out of the body and into the top-level guards, the below fact follows from the properties of CBV:

Lemma 6.12. Let $b \equiv \lambda \bar{x} .\langle\overline{\lfloor p\rfloor \Rightarrow\lfloor e\rfloor}\rangle$ and $f \in R$. For every $\Gamma, R$, and $\theta \in\left(|\Gamma|\right.$, if $\theta \cdot R\left[p_{i}\right] \hookrightarrow{ }^{\star}$ True and $f\left(\overline{\left\lfloor e^{\prime}\right\rfloor}\right) \prec\left\lfloor e_{i}\right\rfloor$, then $\theta \cdot R\left[e_{i}\right] \hookrightarrow^{\star} C\left[f\left(\theta \cdot R\left[\overline{e^{\prime}}\right]\right)\right]$.

Logical Step A pair $f(\bar{t}) \rightsquigarrow f^{\prime}\left(\overline{t^{\prime}}\right)$ is a $\Psi$, $\Phi$-logical step (abbrev. step), if

- $\Psi(f) \equiv \lambda \bar{x} .\langle\overline{p \Rightarrow b}\rangle$,
- SmtValid $\left(\Phi \wedge Q, p_{i}\right)$ for some $(\Psi, \Phi)$-instance $Q$, and
- $f^{\prime}\left(\overline{t^{\prime}}\right)<b_{i}[\bar{t} / \bar{x}]$.

Steps and Reductions Next, using Lemmas 6.12, 6.1, and the definition of logical steps, we show that every logical step corresponds to a sequence of steps in the concrete semantics:
Lemma 6.13 (Step-Reductions). If $f(\overline{\lfloor e\rfloor}) \rightsquigarrow f^{\prime}\left(\overline{\left\lfloor e^{\prime}\right\rfloor}\right)$ is a logical step under $\lfloor R\rfloor,\lfloor\Gamma\rfloor$ and $\theta \in(\Gamma)$, then $f(\overline{\theta \cdot R[e]}) \hookrightarrow^{\star} C\left[f\left(\theta \cdot R\left[\overline{e^{\prime}}\right]\right)\right]$ for some context $C$.

Logical Trace A sequence $f_{0}\left(\overline{t_{0}}\right), f_{1}\left(\overline{t_{1}}\right), f_{2}\left(\overline{t_{2}}\right), \ldots$ is a $\Psi$, $\Phi$-logical trace (abbrev. trace), if $f_{i}\left(\overline{t_{i}}\right) \rightsquigarrow$ $f_{i+1}\left(\overline{t_{i+1}}\right)$ is a $\Psi$, $\Phi$-step, for each $i$. Our termination proof hinges upon the following key result: inhabited environments only have finite logical traces. We prove this result by contradiction. Specifically, we show by Lemma 6.13 that an infinite $(\lfloor R\rfloor,\lfloor\Gamma\rfloor)$-trace combined with the fact that $\Gamma$ is inhabited yields at least one infinite concrete trace, which contradicts the totality assumption. Hence, all the ( $\lfloor R\rfloor,\lfloor\Gamma\rfloor)$ logical traces must be finite.

Theorem 6.14 (Finite-Trace). If $\Gamma$ is inhabited, then every ( $\lfloor R\rfloor,\lfloor\Gamma\rfloor$ )-trace is finite.
Ascending Chains and Traces If unfolding $\Psi$, $\Phi$ yields an infinite chain $\Phi_{0} \subset \ldots \subset \Phi_{n} \ldots$, then $\Psi, \Phi$ has an infinite logical trace. We construct the trace by selecting at level $i\left(i . e\right.$. in $\left.\Phi_{i}\right)$ an application term $f_{i}\left(\overline{t_{i}}\right)$ that was created by unfolding an application term at level $i-1$ (i.e. in $\left.\Phi_{i-1}\right)$.

Lemma 6.15 (Ascending Chains). Let $\Phi_{i} \doteq U_{n f o l d}{ }^{*}(\Psi, \Phi, i)$. If there exists an (infinite) ascending chain $\Phi_{0} \subset \ldots \subset \Phi_{n} \ldots$, then there exists an (infinite) logical trace $f_{0}\left(\overline{t_{0}}\right), \ldots, f_{n}\left(\overline{t_{n}}\right), \ldots$..

Logical Evaluation Terminates Finally, we prove that the proof search procedure PLE terminates. If PLE loops forever, there must be an infinite strictly ascending chain of unfoldings $\Phi_{i}$, and hence, by Lemma 6.15, an infinite logical trace, which, by Theorem 6.14, is impossible.

Theorem 6.16 (Termination). If $\Gamma$ is transparent, then $\operatorname{PLE}(\lfloor R\rfloor,\lfloor\Gamma\rfloor, p)$ terminates.

Table 1. We report verification Time (in seconds, on a 2.3 GHz Intel® Xeon® ${ }^{\circledR}$ CPU E5-2699 v3 with 18 physical cores and 64GiB RAM.), the number of SMT queries and size of Proofs (in lines). The Common columns show sizes of common Implementations and Specifications. We separately consider proofs Without and With PLE Search.

## 7 EVALUATION

We have implemented reflection and PLE in Liquid Haskell [56]. Table 1 summarizes our evaluation which aims to determine (1) the kinds of programs and properties that can be verified, (2) how PLE simplifies writing proofs, and (3) how PLE affects the verification time.
Benchmarks We summarize our benchmarks below, see [58] for details.

- Arithmetic We proved arithmetic properties for the textbook Fibonacci function (c.f. § 2) and the 12 properties of the Ackermann function from [53].
- Class Laws We proved the monoid laws for the Peano, Maybe and List data types and the Functor, Applicative, and Monad laws, summarized in Figure 11, for the Maybe, List and Identity monads.
- Higher Order Properties We used natural deduction to prove textbook logical properties as in §3. We combined natural deduction principles with PLE-search to prove universality of right-folds, as described in [25] and formalized in AGDA [34].
- Functional Correctness We proved correctness of a SAT solver and a unification algorithm as implemented in Zombie [11]. We proved that the SAT solver takes as input a formula $f$ and either returns Nothing or an assignment that satisfies $f$, by reflecting the notion of satisfaction. Then, we proved that if the unification unify $s t$ of two terms $s$ and $t$ returns a substitution su, then applying su to $s$ and $t$ yields identical terms. Note that, while the unification function can itself diverge, and hence cannot be reflected, our method allows terminating and diverging functions to soundly coexist.
- Deterministic Parallelism Retrofitting verification onto an existing language with a mature parallel run-time allows us to create three deterministic parallelism libraries that, for the first time,
verify implicit assumptions about associativity and ordering that are critical for determinism (c.f. [58] for extended description). First, we proved that the ordering laws hold for keys inserted into LVar-style concurrent sets [28]. Second, we used monad-par [33] to implement an $n$-body simulation, whose correctness relied upon proving that a triple of Real (implementing) 3-d acceleration was a Monoid. Third, we built a DPJ-style [10] parallel-reducers library whose correctness relied upon verifying that the reduced arguments form a CommutativeMonoid, and which was the basis of a parallel array sum.

Proof Effort We split the total lines of code of our benchmarks into three categories: Spec represents the refinement types that encode theorems, lemmas, and function specifications; Impl represents the rest of the Haskell code that defines executable functions; Proofs represent the sizes of the Haskell proof terms (i.e. functions returning Prop). Reflection and PLE are optionally enabled using pragmas; the latter is enabled either for a whole file/module or per top-level function.
Runtime Overhead Proof terms have no runtime overhead as they will never be evaluated. When verification of an executable term depends on theorems, we use the below withTheorem function

```
withTheorem :: x:a }->\mathrm{ Prop }->{v:a|v=x
withTheorem x _ = x
```

that inserts the proof argument into the static verification environment, relying upon laziness to not actually evaluate the proof. For example, when verification depends on the associativity of append on the lists xs, ys, and zs, the invocation withTheorem xs (app_assoc xs ys zs) extends the (static) SMT verification environment with the instantiation of the associativity theorem of Figure 1. This invocation adds no runtime overhead, since even though app_assoc xs ys zs is an expensive recursive function, it will never actually get evaluated. To ensure that proof terms are not evaluated in runtime, without using laziness, one can add one rewrite rule for each proof term that replaces the term with unit. For example, the rewrite rule for app_assoc is

```
RULES "assoc/runtime" forall xs ys zs. app_assoc xs ys zs = ()
```

Such rules are sound, since each proof term is total, thus provably reduces to unit.
Results The highlights of our evaluation are the following. (1) Reflection allows for the specification and verification of a wide variety of important properties of programs. (2) PLE drastically reduces the proof effort: by a factor of $2-5 \times$ - shrinking the total lines of proof from 1524 to 638- making it quite modest, about the size of the specifications of the theorems. Since PLE searches for equational properties, there are some proofs, that rarely occur in practice, that PLE cannot simplify, e.g. the logical properties from § 3. (3) PLE does not impose a performance penalty: even though proof search can make an order of magnitude many more SMT queries - increasing the total SMT queries from 1626 without PLE to 4068 with PLE- most of these queries are simple and it is typically faster to type-check the compact proofs enabled by PLE than it is to type-check the $2-5 \times$ longer explicit proofs written by a human.

## 8 RELATED WORK

SMT-Based Verification SMT-solvers have been extensively used to automate program verification via Floyd-Hoare logics [36]. Leon introduces an SMT-based algorithm that is complete for catamorphisms (folds) over ADTs [50] and a semi-decision procedure that is guaranteed to find satisfying assignments (models) for queries over arbitrary recursive functions, if they exist [51]. Our work is inspired by Dafny's Verified Calculations [31] but differs in (1) our use of reflection instead of axiomatization, (2) our use of refinements to compose proofs, and (3) our use of PLE to automate reasoning about user-defined functions. DAFNY (and $\mathrm{F}^{*}$ [52]) encode user-functions as

| Monoid (for Peano, Maybe, List) | Functor (for Maybe, List, Id) |
| :---: | :---: |
| Left Id. mempty $x \diamond \equiv x$ | Id. fmap id $x s \equiv$ id $x s$ |
| Right Id. $x \diamond$ mempty $\equiv x$ | Distr. fmap $(g \circ h) x s \equiv(f m a p g \circ f m a p h) x s$ |
| Assoc. $(x \diamond y) \diamond z \equiv x \diamond(y \diamond z)$ |  |
| Applicative (for Maybe, List, Id) | Monad (for Maybe, List, Id) |
| Id. pure id $\circledast v \equiv v$ | Left Id. return $a \gg=f \equiv f a$ |
| Comp. pure $(0) \circledast u \circledast v \circledast w \equiv u \circledast(v \circledast w)$ | Right Id. $m \gg=$ return $\equiv m$ |
| Hom. pure $f \circledast$ pure $x \equiv$ pure ( $f x$ ) | Assoc. $(m \gg=f) \gg=g \equiv m \gg=(\lambda x \rightarrow f x \gg=g)$ |
| Inter. $u *$ pure $y \equiv$ pure $(\$ y) \circledast u$ |  |
| Ord (for Int, Double, Either, (, )) | Commutative Monoid (for Int, Double, (, )) |
| Refl. $x \leq x$ | Comm. $x \diamond y \equiv y \diamond x$ |
| Antisym. $x \leq y \wedge y \leq x \Longrightarrow x \equiv y$ |  |
| Trans. $x \leq y \wedge y \leq z \Longrightarrow x \leq z$ | (including Monoid laws) |
| Total. $x \leq y \vee y \leq x$ |  |

Fig. 11. Summary of Verified Typeclass Laws.
axioms and use a fixed fuel to instantiate functions upto some fixed unfolding depth [1]. While the fuel-based approach is incomplete, even for equational or calculational reasoning, it may, although rare in practice, quickly time out after a fixed, small number of instantiations rather than perform an exhaustive proof search like PLE. Nevertheless, PLE demonstrates that it is possible to develop complete and practical algorithms for reasoning about user-defined functions.
Proving Equational Properties Several authors have proposed tools for proving (equational) properties of (functional) programs. Systems of Sousa and Dillig [48] and Asada et al. [3] extend classical safety verification algorithms, respectively based on Floyd-Hoare logic and refinement types, to the setting of relational or $k$-safety properties that are assertions over $k$-traces of a program. Thus, these methods can automatically prove that certain functions are associative, commutative etc. but are restricted to first-order properties and are not programmer-extensible. Zeno [47] generates proofs by term rewriting and Halo [60] uses an axiomatic encoding to verify contracts. Both the above are automatic, but unpredictable and not programmer-extensible, hence, have been limited to far simpler properties than the ones checked here. HERMIT [22] proves equalities by rewriting the GHC core language, guided by user specified scripts. Our proofs are Haskell programs, SMT solvers automate reasoning, and importantly, we connect the validity of proofs with the semantics of the programs.
Dependent Types in Programming Integration of dependent types into Haskell has been a long standing goal [21] that dates back to Cayenne [4], a Haskell-like, fully dependent type language with undecidable type checking. Our approach differs significantly in that reflection and PLE use SMT-solvers to drastically simplify proofs over decidable theories. Zombie [46] investigates the design of a dependently typed language where SMT-style congruence closure is used to reason about the equality of terms. However, Zombie explicitly eschews type-level computation, as the authors write "equalities that follow from $\beta$-reduction" are "incompatible with congruence closure". Due to this incompleteness, the programmer must use explicit @join@ terms to indicate where normalization should be triggered, even so, equality checking is based on fuel, hence, is incomplete.
Theorem Provers Reflection shows how to retrofit deep specification and verification in the style of Agda [38], Coo [7] and Isabelle [37] into existing languages via refinement typing and PLE shows how type-level computation can be made compatible with SMT solvers' native theory reasoning
yielding a powerful new way to automate proofs (§ 2.5). An extensive comparison [54] between our approach and mature theorem provers like CoQ, Agda, and Isabelle reveals that these provers have two clear advantages over our approach: they emit certificates, so they rely on a small trusted computing base, and they have decades-worth of tactics, libraries, and proof scripts that enable large scale proof engineering. Some tactics even enable embedding of SMT-based proof search heuristics, e.g. Sledgehammer [9], that is widely used in Isabelle. However, this search does not have the completeness guarantees of PLE. The issue of extracting checkable certificates from SMT solvers is well understood $[12,35]$ and easy to extend to our setting. However, the question of extending SMT-based verifiers with tactics and scriptable proof search, and more generally, incorporating interactivity in the style of proof-assistants, perhaps enhanced by proof-completion hints, remains an interesting direction for future work.

## 9 CONCLUSIONS AND FUTURE WORK

Our results identify a new design for deductive verifiers wherein: (1) via Refinement Reflection, we can encode natural deduction proofs as SMT-checkable refinement typed programs and (2) via Proof by Logical Evaluation we can combine the complementary strengths of SMT- (i.e., decision procedures) and TT- based approaches (i.e., type-level computation) to obtain completeness guarantees when verifying properties of user-defined functions. However, the increased automation of SMT and proof-search can sometimes make it harder for a user to debug failed proofs. In future work, it would be interesting to investigate how to add interactivity to SMT based verifiers, in the form of tactics and scripts or algorithms for synthesizing proof hints, and to design new ways to explain and fix refinement type errors.

## ACKNOWLEDGMENTS

We thank the anonymous referees, our shepherd Koen Claessen, and Rustan Leino for their feedback on earlier versions of this paper. Special thanks to George Karachalias and Valentin Robert for their input on proof combinators, and to Joachim Breitner and Eric Seidel for their suggestion on run-time proof elimination. This work was supported by the EPSRC programme grant EP/K034413/1, the National Science Foundation under Grant Numbers CCF-1618756, CNS-1518765, CCF-1518844, CCF-1422471, CCF-1223850, and CCF-1218344, and a generous gift from Microsoft Research.

## B PROOFS FOR PLE

Proofs for § 6
Proof. (Of lemma 6.5) We prove the result by induction on $n$.
Case $n=0$ : Immediate as $t \equiv t^{\prime}$.
Case $n=k+1$ : Consider any $t^{\prime}$ such that $\operatorname{SmtValid}\left(\Phi_{k+1}, v=t^{\prime}\right)$. By definition $\Phi_{k+1}=$ $\operatorname{Unfold}\left(\Psi, \Phi_{k}\right)$, hence $\operatorname{SmtValid}\left(\operatorname{Unfold}\left(\Psi, \Phi_{k}\right), v=t, v=t^{\prime}\right)$. Consider any $f\left(\overline{t^{\prime}}\right)<t^{\prime} ;$ Lemma 6.6 completes the proof.

Proof. (Of lemma 6.6) Proof by induction on the structure of $t^{\prime}$ : Case $t^{\prime} \equiv x$ : There are no subterms, hence immediate. Case $t^{\prime} \equiv c$ : There are no subterms, hence immediate. Case $t^{\prime} \equiv f\left(\overline{t^{\prime}}\right)$ : Consider the last link in $\Phi$ connecting the equivalence class of $v$ (and $t$ ) to $t^{\prime}$. Suppose the last link is a congruence link of the form $t=t^{\prime}$ where $t \equiv f(\bar{t})$ and $\operatorname{SmtValid}\left(\Phi, t=t^{\prime}\right)$. Then $\underline{f}(\bar{t})<\Phi, t$ and we are done. Suppose instead, the last link is an equality link in $\Phi$ of the form $z=f\left(\overline{t^{\prime}}\right)$. In this case, $f\left(\overline{t^{\prime}}\right)<\Phi$ and again, we are done.

Proof. (Of lemma 6.7)
Let $G_{k} \doteq$ Unfold ${ }^{*}(\Psi, \Phi, k)$. Let us assume that

$$
\begin{equation*}
\left.\operatorname{SmtValid}^{(U n f o l d}{ }^{*}(\Psi, \Phi, v=t, n), v=t^{\prime}\right) \tag{3}
\end{equation*}
$$

Consider any instance

$$
\begin{equation*}
q \equiv f\left(\overline{t^{\prime}}\right)=b_{i}\left[\overline{t^{\prime}} / \bar{x}\right] \text { in } \operatorname{Unfold}\left(\Psi, \Phi \wedge v=t^{\prime}\right) \tag{4}
\end{equation*}
$$

By the definition of Unfold, we have

$$
\begin{equation*}
f\left(\overline{t^{\prime}}\right)<\Phi \wedge v=t^{\prime} \text { such that } \operatorname{Smt} \operatorname{Valid}\left(\Phi, p_{i}\left[\overline{t^{\prime}} / \bar{x}\right]\right) \tag{5}
\end{equation*}
$$

By (3) and Lemma 6.5 there exists $f(\bar{t}) \prec \Phi_{n}$ such that

$$
\operatorname{SmtValid}\left(\Phi_{n}, t=t^{\prime}\right)
$$

As $\Phi \subseteq \Phi_{n}$ and (5), by congruence

$$
\operatorname{SmtValid}\left(\Phi_{n}, p_{i}[\bar{t} / \bar{x}]\right)
$$

Hence, the instance

$$
f(\bar{t})=b_{i}[\bar{t} / \bar{x}] \text { is } \operatorname{in} \Phi_{n+1}
$$

That is

$$
\operatorname{Smt} \operatorname{Valid}\left(\Phi_{n+1}, t=t^{\prime} \wedge f(\bar{t})=b_{i}[t / x]\right)
$$

And so by congruence closure

$$
\operatorname{SmtValid}\left(\Phi_{n+1}, q\right)
$$

As the above holds for every instance, we have

$$
\operatorname{Smt} \operatorname{Valid}\left(\Phi_{n+1}, \operatorname{Unfold}\left(\Psi, \Phi \wedge v=t^{\prime}\right)\right)
$$

Proof. (Of lemma 6.8) The proof follows by induction on the structure of $\Psi, \Phi \vdash t \rightarrow t^{\prime}$.
Base Case EQ-Refl: Follows immediately as $t \equiv t^{\prime}$.
Inductive Case EQ-Trans
In this case, there exists $t^{\prime \prime}$ such that

$$
\begin{align*}
& \Psi, \Phi \vdash t \rightarrow t^{\prime \prime}  \tag{6}\\
& \operatorname{SmtValid}\left(\operatorname{Unfold}\left(\Psi, \Phi \wedge v=t^{\prime \prime}\right), v=t^{\prime}\right) \tag{7}
\end{align*}
$$

By the induction hypothesis (6) implies there exists $0 \leq n$ such that

$$
\operatorname{SmtValid}\left(\operatorname{Unfold}^{*}(\Psi, \Phi \wedge v=t, n), v=t^{\prime \prime}\right)
$$

By Lemma 6.7 we have

$$
\operatorname{SmtValid}\left(\operatorname{Unfold}^{*}(\Psi, \Phi, v=t, n+1), \operatorname{Unfold}\left(\Psi, \Phi \wedge v=t^{\prime \prime}\right)\right)
$$

Thus, by (7) and modus ponens we get

$$
\operatorname{SmtValid}\left(\operatorname{Unfold}^{*}(\Psi, \Phi, v=t, n+1), v=t^{\prime}\right)
$$

Proof. (Of Lemma 6.9) Let $\Phi^{\prime}=\Phi \wedge v=t$.
Case $\Rightarrow$ : Assume that $\operatorname{PLE}\left(\Psi, \Phi, t=t^{\prime}\right)$. That is, at some iteration $i$ we have $\operatorname{SmtValid}\left(\Phi_{i}, v=t^{\prime}\right)$, i.e. by (6.2) we have $\operatorname{SmtValid}\left(U^{\prime}\right.$ nfold $\left.^{*}\left(\Psi, \Phi^{\prime}, i\right), v=t^{\prime}\right)$.

Case $\Leftarrow$ :Pick the smallest $n$ such that SmtValid(Unfold* $\left.\left(\Psi, \Phi^{\prime}, n\right), v=t^{\prime}\right)$. Using Lemmas 6.3 and 6.4 we can then show that forall $0 \leq k<n$, we have

$$
\operatorname{Unfold}^{*}\left(\Psi, \Phi^{\prime}, k\right) \subset \operatorname{Unfold}^{*}\left(\Psi, \Phi^{\prime}, k+1\right)
$$

and

$$
\text { Unfold }^{*}\left(\Psi, \Phi^{\prime}, k\right) \nvdash v=t^{\prime}
$$

Hence, after $n$ iterations of the recursive loop, $\operatorname{PLE}\left(\Psi, \Phi, t=t^{\prime}\right)$, returns true.

Steps and Values Next, we show that if $f(\bar{y}) \rightsquigarrow t^{\prime}$ is a logical step under an $\Gamma$ that is inhabited by $\theta$ then $f(\bar{y})$ reduces to a value under $\theta$. The proof follows by observing that if $\Gamma$ is inhabited by $\theta$, and a particular step is possible, then the guard corresponding to that step must also be true under $\theta$ and hence, by totality, the function must reduce to a value under the given store.

Lemma B. 1 (Step-Value). If $\theta \in\left(\Gamma \mid\right.$ and $f(\bar{y}) \rightsquigarrow t^{\prime}$ is a $\lfloor R\rfloor,\lfloor\Gamma\rfloor$ step then $R[\theta \cdot f(\bar{y})] \hookrightarrow^{\star} v$.
Proof. (Of Lemma B.1)

$$
\begin{align*}
\text { Assume that } & \theta \in(\Gamma\rangle  \tag{8}\\
\text { Let } & \theta^{*} \doteq \theta[\bar{x} \mapsto \theta \cdot \bar{y}]  \tag{9}\\
& \Psi(f) \doteq \lambda \bar{x} \cdot\langle\overline{p \Rightarrow b}\rangle \tag{10}
\end{align*}
$$

As $f(\bar{y}) \rightsquigarrow t^{\prime}$ is a $\lfloor R\rfloor \Gamma$ step, for some $i,\lfloor R\rfloor$-instance $Q$ we have

$$
\begin{align*}
& \operatorname{SmtValid}\left(\lfloor\Gamma\rfloor \wedge Q, p_{i}[\bar{y} / \bar{x}]\right) \\
\text { Hence, by (8) and Lemma 6.1 } & \theta \cdot R\left[p_{i}[\bar{y} / \bar{x}]\right] \hookrightarrow^{\star} \text { True }  \tag{11}\\
\text { As } & \theta^{*} \cdot p_{i} \equiv \theta \cdot p_{i}[\bar{y} / \bar{x}]  \tag{12}\\
\text { The fact (11) yields } & \theta^{*} \cdot R\left[p_{i}\right] \hookrightarrow^{\star} \text { True } \\
\text { By the Totality Assumption 6.11 } & R\left[\theta^{*} \cdot f(\bar{x})\right] \hookrightarrow^{\star} v \\
\text { That is } & R[\theta \cdot f(\bar{y})] \hookrightarrow^{\star} v \tag{13}
\end{align*}
$$

Divergence A closed term $t$ diverges under $R$ if there is no $v$ such that $R[t] \hookrightarrow^{\star} v$.
Lemma B. 2 (Divergence). If $\forall 0 \leq i$ we have $R\left[t_{i}\right] \hookrightarrow{ }^{\star} C\left[t_{i+1}\right]$ then $t_{0}$ diverges under $\Psi$.
Proof. (Of Theorem 6.14)

$$
\begin{array}{rl}
\text { Assume that } & \theta \in(\Gamma\rceil \\
\text { and assume an infinite }\lfloor R\rfloor,\lfloor\Gamma\rfloor \text { trace: } & f_{0}\left(\overline{t_{0}}\right), f_{1}\left(\overline{t_{1}}\right), \ldots \\
\text { Where additionally } & \overline{t_{0}} \equiv \overline{x_{0}} \\
\text { Define } & t_{i}^{*} \equiv \theta \cdot f_{i}\left(\overline{t_{i}}\right) \\
\text { By Lemma 6.13, for every } i \in \mathbb{N} & R\left[t_{i}^{*}\right] \hookrightarrow^{\star} C_{i}\left[t_{i+1}^{*}\right] \\
\text { Hence, by Lemma B. } 2 & t_{0}^{*} \text { diverges under } \Psi \\
\text { i.e., by (17, 18) } & \theta \cdot f_{0}\left(\overline{x_{0}}\right) \text { diverges under } \Psi  \tag{19}\\
\text { But by (15) and Lemma B.1 } & R\left[\theta \cdot f_{0}\left(\overline{x_{0}}\right)\right] \hookrightarrow^{\star} v \quad \text { contradicting (19) }
\end{array}
$$

Hence, assumption (16) cannot hold, i.e. all all the $\Psi, \Phi$ symbolic traces must be finite.
Proof. (Of Theorem 6.16) As $\Phi$ is transparent, there are two cases.
Case: $\Gamma$ is inconsistent.

| By definition of inconsistency | $\operatorname{SmtValid}(\lfloor\Gamma\rfloor$, false $)$ |
| ---: | :--- |
| Hence | $\operatorname{SmtValid}(\lfloor\Gamma\rfloor, p)$ |
| That is | $\operatorname{PLE}(\lfloor R\rfloor,\lfloor\Gamma\rfloor, p)$ terminates immediately. |

Case: $\Gamma$ is inhabited.

$$
\begin{equation*}
\text { That is, exists } \theta \text { s.t. } \quad \theta \in(Г) \tag{20}
\end{equation*}
$$

Suppose that $\operatorname{PLE}(\lfloor R\rfloor,\lfloor\Gamma\rfloor, p)$ does not terminate.
That is, there is an infinitely increasing chain: $\Phi_{0} \subset \ldots \subset \Phi_{n} \ldots$
By Lemma $6.15\lfloor R\rfloor,\lfloor\Gamma\rfloor$ has an infinite trace
Which, by (20) contradicts Theorem 6.14. Thus, (21) is impossible, i.e. $\operatorname{PLE}(\lfloor R\rfloor,\lfloor\Gamma\rfloor, p)$ terminates.

## C PROOF OF SECTION: EMBEDDING NATURAL DEDUCTION WITH REFINEMENT TYPES

Lemma C. 1 (Validity). If there exists $e \in(|\phi|$ then $\phi$ is valid.
Proof. We prove the lemma by case analysis in the shape of $\phi$.

- $\phi \equiv\{p\}$. Since the set $\mathbb{\{} p\}\})=\left\{e \mid p \hookrightarrow^{\star}\right.$ True $\}$ is not empty, then $p \hookrightarrow^{\star}$ True.
- $\phi \equiv \phi_{1} \rightarrow \phi_{2}$. By assumption, there exists an expressions $f$ so that $\forall e_{x} \in\left(\left|\phi_{1}\right|\right), f e_{x} \in\left(\phi_{2}\right)$. So, if there exists an expression $e_{1} \in\left(\phi_{1} \mid\right.$ that makes $\phi_{1}$ valid then $f e_{1}$ makes $\phi_{2}$ valid.
- $\phi \equiv \phi \rightarrow$ False. By assumption, there exists an expressions $f$ so that $\forall e_{x} \in(\phi), f e_{x} \in$ ( \{ False \}). So, if there exists an expression $e_{1} \in(\mid \phi)$ that makes $\phi$ valid then $f e_{1}$ makes \{ False \} valid, which is impossible, thus $\phi$ cannot be valid.
- $\phi \equiv\left(\phi_{1}, \phi_{2}\right)$. If there exists a total expression $e \in(\phi \mid)$ then $e$ evaluates to $\left(e_{1}, e_{2}\right)$.
- $\phi \equiv$ Either $\phi_{1} \phi_{2}$. If there exists a total expression $e \in\left(\phi \mid\right.$ ) then $e$ evaluates to either Left $e^{\prime}$ or Right $e^{\prime}$.
- $\phi \equiv x: \tau \rightarrow \phi$. By assumption, there exists an expressions $f$ so that $\forall e_{x} \in \ \tau D, f e_{x} \in$ $\left(\mid \phi\left[x / e_{x}\right]\right)$. So, if there exists an expression $e_{1} \in(\tau \tau)$ then $f e_{1}$ makes $\phi\left[x / e_{1}\right]$ valid.
- $\phi \equiv(x:: \tau, \phi)$. By assumption, there exists an expressions $p$ that evaluates to a pair $\left(e_{x}, e_{y}\right)$ so that $e_{x} \in(\tau)$ and $e_{y} \in\left(\phi\left[x / e_{x}\right]\right)$.

Theorem C. 2 (Validity). If $\emptyset ; \emptyset \vdash e: \phi$ then $\phi$ is valid.
Proof. By direct implication of Lemma C. 1 and soundness of $\lambda^{R}$ (Theorem 4.1).

## D REFINEMENT REFLECTION: $\lambda^{R}$ : EXTENDED VERSION WITH PROOFS

Our first step towards formalizing refinement reflection is a core calculus $\lambda^{R}$ with an undecidable type system based on denotational semantics. We show how the soundness of the type system allows us to prove theorems using $\lambda^{R}$.

## D. 1 Syntax

Figure 12 summarizes the syntax of $\lambda^{R}$, which is essentially the calculus $\lambda^{U}$ [56] with explicit recursion and a special reflect binding form to denote terms that are reflected into the refinement logic. In $\lambda^{R}$ refinements $r$ are arbitrary expressions $e$ (hence $r::=e$ in Figure 12). This choice allows us to prove preservation and progress, but renders typechecking undecidable. In § F we will see how to recover decidability by soundly approximating refinements.

The syntactic elements of $\lambda^{R}$ are layered into primitive constants, values, expressions, binders and programs.

$$
\begin{array}{rcc}
\text { Operators } & \odot & ::= \\
\text { Constants } & c & ::=\wedge|<||\odot|+,-, \ldots \\
& & \mid \\
\text { True } \mid \text { False } \mid 0,1,-1, \ldots \\
\text { Values } & w & ::=c|\lambda x . e| D \bar{w} \\
\text { Expressions } & e & ::= \\
& & |x| x \mid e e \\
\text { Binders } & b & ::= \\
\text { case } x=e \text { of }\{D \bar{x} \rightarrow e\} \\
\text { Program } & p & ::= \\
\text { let rec } x: \tau=b \text { in } b \\
\text { Basic Types } & B & ::= \\
\text { Int } \mid \text { Bool } x: \tau=e \text { in } p \\
\text { Refined Types } & \tau & ::= \\
& \{v: B|\{ \}| \mid\} x: \tau \rightarrow \tau
\end{array}
$$

Fig. 12. Syntax of $\lambda^{R}$

## Contexts

$$
\begin{aligned}
C::= & \bullet \\
& |C e| c C \mid D \bar{e} C \bar{e} \\
& \mid \text { case } y=C \text { of }\left\{D_{i} \bar{x} \rightarrow e_{i}\right\}
\end{aligned}
$$

## Reductions

$$
\begin{aligned}
C[p] & \hookrightarrow C\left[p^{\prime}\right], \quad \text { if } p \hookrightarrow p^{\prime} \\
c v & \hookrightarrow \delta(c, v) \\
(\lambda x . e) e^{\prime} & \hookrightarrow e\left[e^{\prime} / x\right] \\
\text { case } y=D_{j} \bar{e} \text { of }\left\{D_{i} \overline{x_{i}} \rightarrow e_{i}\right\} & \hookrightarrow e_{j}\left[D_{j} \bar{e} / y\right]\left[\bar{e} / \overline{x_{i}}\right] \\
\text { reflect } x: \tau=e \text { in } p & \hookrightarrow p[\text { fix }(\lambda x . e) / x] \\
\text { let rec } x: \tau=b_{x} \text { in } b & \hookrightarrow b\left[\text { fix }\left(\lambda x . b_{x}\right) / x\right] \\
\text { fix } p & \hookrightarrow p(\text { fix } p)
\end{aligned}
$$

Fig. 13. Operational Semantics of $\lambda^{R}$

Constants The primitive constants of $\lambda^{R}$ include all the primitive logical operators $\oplus$, here, the set $\{=,<\}$. Moreover, they include the primitive booleans True, False, integers $-1,0,1$, etc., and logical operators $\wedge, \vee,!$, etc..
Data Constructors We encode data constructors as special constants. For example the data type [Int], which represents finite lists of integers, has two data constructors: [] ("nil") and : ("cons").
Values \& Expressions The values of $\lambda^{R}$ include constants, $\lambda$-abstractions $\lambda x . e$, and fully applied data constructors $D$ that wrap values. The expressions of $\lambda^{R}$ include values and variables $x$, applications e e and case expressions.
Binders \& Programs A binder $b$ is a series of possibly recursive let definitions, followed by an expression. A program $p$ is a series of reflect definitions, each of which names a function that can be reflected into the refinement logic, followed by a binder. The stratification of programs via binders is required so that arbitrary recursive definitions are allowed but cannot be inserted into the logic via refinements or reflection. (We can allow non-recursive let binders in $e$, but omit them for simplicity.)

## D. 2 Operational Semantics

Figure 12 summarizes the small step contextual $\beta$-reduction semantics for $\lambda^{R}$. We write $e \hookrightarrow^{j} e^{\prime}$ if there exist $e_{1}, \ldots, e_{j}$ such that $e$ is $e_{1}, e^{\prime}$ is $e_{j}$ and $\forall i, j, 1 \leq i<j$, we have $e_{i} \hookrightarrow e_{i+1}$. We write $e \hookrightarrow^{\star} e^{\prime}$ if there exists some finite $j$ such that $e \hookrightarrow^{j} e^{\prime}$. We define $\approx_{\beta}$ to be the reflexive, symmetric, transitive closure of $\hookrightarrow$.
Constants Application of a constant requires the argument be reduced to a value; in a single step the expression is reduced to the output of the primitive constant operation. For example, consider $=$, the primitive equality operator on integers. We have $\delta(=, n) \doteq={ }_{n}$ where $\delta\left(=_{n}, m\right)$ equals True iff $m$ is the same as $n$. We assume that the equality operator is defined for all values, and, for functions, is defined as extensional equality. That is, for all $f$ and $f^{\prime}$ we have $\left(f=f^{\prime}\right) \hookrightarrow$ True iff $\forall v . f v \approx_{\beta} f^{\prime} v$. We assume source terms only contain implementable equalities over non-function types; the above only appears in refinements and allows us to state and prove facts about extensional equality § H.2.

## D. 3 Types

$\lambda^{R}$ types include basic types, which are refined with predicates, and dependent function types. Basic types $B$ comprise integers, booleans, and a family of data-types $T$ (representing lists, trees etc..) For example the data type [Int] represents lists of integers. We refine basic types with predicates (boolean valued expressions e) to obtain basic refinement types $\{v: B \mid e\}$. Finally, we have dependent function types $x: \tau_{x} \rightarrow \tau$ where the input $x$ has the type $\tau_{x}$ and the output $\tau$ may refer to the input binder $x$. We write $B$ to abbreviate $\{v: B \mid$ True $\}$, and $\tau_{x} \rightarrow \tau$ to abbreviate $x: \tau_{x} \rightarrow \tau$ if $x$ does not appear in $\tau$. We use $r$ to refer to refinements.

Denotations Each type $\tau$ denotes a set of expressions $\llbracket \tau \rrbracket$, that are defined via the dynamic semantics [27]. Let shape $(\tau)$ be the type we get if we erase all refinements from $\tau$ and $e: \operatorname{shape}(\tau)$ be the standard typing relation for the typed lambda calculus. Then, we define the denotation of types as:

$$
\begin{aligned}
& \llbracket\{x: B \mid r\} \rrbracket \doteq\left\{e \mid e: B, \text { if } e e^{\star} w \text { then } r[x / w] \hookrightarrow^{\star} \text { True }\right\} \\
& \llbracket x: \tau_{x} \rightarrow \tau \rrbracket \doteq\left\{e \mid e: \operatorname{shape}\left(\tau_{x} \rightarrow \tau\right), \forall e_{x} \in \llbracket \tau_{x} \rrbracket . e e_{x} \in \llbracket \tau\left[x / e_{x}\right] \rrbracket\right\}
\end{aligned}
$$

Constants For each constant $c$ we define its type prim(c) such that $c \in \llbracket \operatorname{prim}(c) \rrbracket$. For example,

$$
\begin{array}{ll}
\operatorname{prim}(3) & \doteq\{v: \operatorname{Int} \mid v=3\} \\
\operatorname{prim}(+) & \doteq \mathrm{x}: \operatorname{Int} \rightarrow \mathrm{y}: \text { Int } \rightarrow\{v: \text { Int } \mid v=x+y\} \\
\operatorname{prim}(\leq) & \doteq \mathrm{x}: \text { Int } \rightarrow \mathrm{y}: \text { Int } \rightarrow\{v: \operatorname{Bool} \mid v \Leftrightarrow x \leq y\}
\end{array}
$$

So, by definition we get the constant typing lemma
Lemma D.1. [Constant Typing] Every constant $c \in \llbracket p r i m(c) \rrbracket$.
Thus, if $\operatorname{prim}(c) \doteq x: \tau_{x} \rightarrow \tau$, then for every value $w \in \llbracket \tau_{x} \rrbracket$, we require $\delta(c, w) \in \llbracket \tau[x / w] \rrbracket$.

## D. 4 Refinement Reflection

The simple, but key idea in our work is to strengthen the output type of functions with a refinement that reflects the definition of the function in the logic. We do this by treating each reflect-binder: reflect $f: \tau=e$ in $p$ as a let rec-binder: let rec $f: \operatorname{Reflect}(\tau, e)=e$ in $p$ during type checking (rule T-Refl in Figure 7).

Reflection We write $\operatorname{Reflect}(\tau, e)$ for the reflection of term $e$ into the type $\tau$, defined by strengthening $\tau$ as:

$$
\begin{array}{ll}
\operatorname{Reflect}(\{v: B \mid r\}, e) & \doteq=\{v: B \mid r \wedge v=e\} \\
\operatorname{Reflect}\left(x: \tau_{x} \rightarrow \tau, \lambda y . e\right) & \doteq x: \tau_{x} \rightarrow \operatorname{Reflect}(\tau, e[y / x])
\end{array}
$$

As an example, recall from § 2 that the reflect fib strengthens the type of fib with the reflected refinement fibp.
Consequences for Verification Reflection has two consequences for verification. First, the reflected refinement is not trusted; it is itself verified (as a valid output type) during type checking. Second, instead of being tethered to quantifier instantiation heuristics or having to program "triggers" as in Dafny [29] or $\mathrm{F}^{*}$ [52] the programmer can predictably "unfold" the definition of the function during a proof simply by "calling" the function, which we have found to be a very natural way of structuring proofs § 7 .

## D. 5 Refining \& Reflecting Data Constructors with Measures

We assume that each data type is equipped with a set of measures which are unary functions whose (1) domain is the data type, and (2) body is a single case-expression over the datatype [56]:

$$
\text { measure f: } \tau=\lambda x \text {.case } y=x \text { of }\left\{D_{i} \bar{z} \rightarrow e_{i}\right\}
$$

For example, len measures the size of an [Int]:

```
measure len :: [Int] }->\mathrm{ Nat
len = \x }->\mathrm{ case }x\mathrm{ of
    [] }->
    (x:xs) }->1+1en x
```

Checking and Projection We assume the existence of measures that check the top-level constructor, and project their individual fields. In § F. 2 we show how to use these measures to reflect functions over datatypes. For example, for lists, we assume the existence of measures:

```
isNil [] = True
isNil (x:xs) = False
isCons (x:xs) = True
isCons [] = False
sel1 (x:xs) = x
sel2 (x:xs) = xs
```

Refining Data Constructors with Measures We use measures to strengthen the types of data constructors, and we use these strengthened types during construction and destruction (patternmatching). Let: (1) $D$ be a data constructor, with unrefined type $\bar{x}: \bar{\tau} \rightarrow T$ (2) the $i$-th measure definition with domain $T$ is:

$$
\text { measure } \mathrm{f}_{\mathrm{i}}: \tau=\lambda x \text {.case } y=x \text { of }\left\{D \bar{z} \rightarrow e_{i}\right\}
$$

Then, the refined type of $D$ is defined:

$$
\operatorname{prim}(D) \doteq \bar{x}: \bar{\tau} \rightarrow\left\{v: T \mid \wedge_{i} f_{i} v=e_{i}[\bar{x} / \bar{z}]\right\}
$$

Thus, each data constructor's output type is refined to reflect the definition of each of its measures. For example, we use the measures len, isNil, isCons, sel1, and sel2 to strengthen the types of []
and : to:

$$
\begin{aligned}
\operatorname{prim}([]) & \doteq\left\{v:[\operatorname{Int}] \mid r_{\square}\right\} \\
\operatorname{prim}(:) & \doteq x: \operatorname{Int} \rightarrow x s:[\operatorname{Int}] \rightarrow\left\{v:[\operatorname{Int}] \mid r_{:}\right\}
\end{aligned}
$$

where the output refinements are

$$
\begin{aligned}
r_{[]} & \doteq \text { len } v=0 \wedge \text { isNil } v \wedge!\text { isCons } v \\
r_{:} & \doteq \text { len } v=1+\operatorname{len} x s \wedge!\text { isNil } v \wedge \text { isCons } v \\
& \wedge \text { sel } v=x \wedge \operatorname{sel} 2 v=x s
\end{aligned}
$$

It is easy to prove that Lemma D. 1 holds for data constructors, by construction. For example, len [] $=0$ evaluates to true.

## D. 6 Typing Rules

Next, we present the type-checking judgments and rules of $\lambda^{R}$.
Environments and Closing Substitutions A type environment $\Gamma$ is a sequence of type bindings $x_{1}: \tau_{1}, \ldots, x_{n}: \tau_{n}$. An environment denotes a set of closing substitutions $\theta$ which are sequences of expression bindings: $x_{1} \mapsto e_{1}, \ldots, x_{n} \mapsto e_{n}$ such that:

$$
\llbracket \Gamma \rrbracket \doteq\{\theta \mid \forall x: \tau \in \Gamma \cdot \theta(x) \in \llbracket \theta \cdot \tau \rrbracket\}
$$

Judgments We use environments to define three kinds of rules: Well-formedness, Subtyping, and Typing [27,56]. A judgment $\Gamma \vdash \tau$ states that the refinement type $\tau$ is well-formed in the environment $\Gamma$. Intuitively, the type $\tau$ is well-formed if all the refinements in $\tau$ are Bool-typed in $\Gamma$. A judgment $\Gamma \vdash \tau_{1} \leq \tau_{2}$ states that the type $\tau_{1}$ is a subtype of $\tau_{2}$ in the environment $\Gamma$. Informally, $\tau_{1}$ is a subtype of $\tau_{2}$ if, when the free variables of $\tau_{1}$ and $\tau_{2}$ are bound tomeasures expressions described by $\Gamma$, the denotation of $\tau_{1}$ is contained in the denotation of $\tau_{2}$. Subtyping of basic types reduces to denotational containment checking. That is, for any closing substitution $\theta$ in the denotation of $\Gamma$, for every expression $e$, if $e \in \llbracket \theta \cdot \tau_{1} \rrbracket$ then $e \in \llbracket \theta \cdot \tau_{2} \rrbracket$. A judgment $\Gamma \vdash p: \tau$ states that the program $p$ has the type $\tau$ in the environment $\Gamma$. That is, when the free variables in $p$ are bound to expressions described by $\Gamma$, the program $p$ will evaluate to a value described by $\tau$.
Rules All but three of the rules are standard [27, 56]. First, rule T-Refl is used to strengthen the type of each reflected binder with its definition, as described previously in § D.4. Second, rule T-Exact strengthens the expression with a singleton type equating the value and the expression (i.e. reflecting the expression in the type). This is a generalization of the "selfification" rules from [27, 39], and is required to equate the reflected functions with their definitions. For example, the application (fib 1 ) is typed as $\{v:$ Int $\mid$ fibP $v 1 \wedge v=$ fib 1$\}$ where the first conjunct comes from the (reflection-strengthened) output refinement of fib § 2, and the second conjunct comes from rule T-Еxact. Finally, rule T-Fix is used to type the intermediate fix expressions that appear, not in the surface language but as intermediate terms in the operational semantics.
Soundness Following $\lambda^{U}$ [56], we can show that evaluation preserves typing and that typing implies denotational inclusion.
Theorem D.2. [Soundness of $\lambda^{R}$ ]

- Denotations If $\Gamma \vdash p: \tau$ then $\forall \theta \in \llbracket \Gamma \rrbracket . \theta \cdot p \in \llbracket \theta \cdot \tau \rrbracket$.
- Preservation If $\vdash \vdash: \tau$ and $p \hookrightarrow^{\star} w$ then $\emptyset \vdash w: \tau$.

## Typing

$$
\begin{aligned}
& \frac{x: \tau \in \Gamma}{\Gamma \vdash x: \tau} \text { T-VAR } \quad \text { T-Con } \\
& \frac{\Gamma \vdash p: \tau^{\prime} \quad \Gamma \vdash \tau^{\prime} \leq \tau}{\Gamma \vdash p: \tau} \text { T-SUB } \\
& \frac{\Gamma \vdash e:\{v: B \mid\{\mid r\}\}}{\Gamma \vdash e:\{v: B \mid\{\mid r\} \wedge v=e\}} \text { т-Ехаст } \\
& \frac{\Gamma, x: \tau_{x}+e: \tau}{\Gamma \vdash \lambda x . e: x: \tau_{x} \rightarrow \tau}{ }^{\mathrm{T}-\mathrm{FUN}} \\
& \frac{\Gamma \vdash e_{1}:\left(x: \tau_{x} \rightarrow \tau\right) \quad \Gamma \vdash e_{2}: \tau_{x}}{\Gamma \vdash e_{1} e_{2}: \tau} \text { T-APP } \\
& \Gamma, x: \tau_{x} \vdash b_{x}: \tau_{x} \quad \Gamma, x: \tau_{x} \vdash \tau_{x} \\
& \frac{\Gamma, x: \tau_{x} \vdash b: \tau \quad \Gamma \vdash \tau}{\Gamma \vdash \text { let } \operatorname{rec} x: \tau_{x}=b_{x} \text { in } b: \tau} \text { T-Let } \\
& \frac{\Gamma \vdash \operatorname{let} \operatorname{rec} f: \operatorname{Reflect}\left(\tau_{f}, e\right)=e \operatorname{in} p: \tau}{\Gamma \vdash \operatorname{reflect} f: \tau_{f}=e \operatorname{in} p: \tau} \text { T-RefL } \\
& \Gamma \vdash e:\left\{v: T \mid e_{r}\right\} \quad \Gamma \vdash \tau \\
& \forall i . \operatorname{prim}\left(D_{i}\right)=\overline{y_{j}: \tau_{j}} \rightarrow\left\{v: T \mid e_{r_{i}}\right\} \\
& \frac{\Gamma, \overline{y_{j}: \tau_{j}}, x:\left\{v: T \mid e_{r} \wedge e_{r_{i}}\right\} \vdash e_{i}: \tau}{\Gamma \vdash \operatorname{case} x=e \text { of }\left\{D_{i} \overline{y_{i}} \rightarrow e_{i}\right\}: \tau} \text { T-CASE }
\end{aligned}
$$

## Well Formedness

$$
\begin{aligned}
& \frac{\Gamma, v: B \vdash e: B o o l}{} \downarrow \\
& \frac{\Gamma \vdash\{v: B \mid e\}}{}{ }^{\Downarrow} \text { WF-BASE } \\
& \frac{\Gamma \vdash \tau_{x} \quad \Gamma, x: \tau_{x} \vdash \tau}{\Gamma \vdash x: \tau_{x} \rightarrow \tau} \text { WF-FUN }
\end{aligned}
$$

## Subtyping

$$
\begin{gathered}
\begin{array}{c}
\Gamma^{\prime} \doteq \Gamma, v:\left\{B^{\Downarrow} \mid e\right\} \\
\Gamma^{\prime} \vdash e^{\prime} \rightsquigarrow p^{\prime} \quad \operatorname{SmtValid}\left(\left\lfloor\Gamma^{\prime}\right\rfloor \Rightarrow p^{\prime}\right)
\end{array} \\
\begin{array}{c}
\Gamma \vdash\{v: B \mid e\} \leq\left\{v: B \mid e^{\prime}\right\} \\
\frac{\Gamma \vdash \tau_{x}^{\prime} \leq \tau_{x} \quad \Gamma, x: \tau_{x}^{\prime} \vdash \tau \leq \tau^{\prime}}{\Gamma \vdash x: \tau_{x} \rightarrow \tau \leq x: \tau_{x}^{\prime} \rightarrow \tau^{\prime}}
\end{array} \text { ؛-FUN }
\end{gathered}
$$

Fig. 14. Typing of $\lambda^{R}$

## D. 7 From Programs \& Types to Propositions \& Proofs

The denotational soundness Theorem D. 2 lets us interpret well typed programs as proofs of propositions.
"Definitions" A definition $d$ is a sequence of reflected binders:

$$
d::=\text { • | reflect } x: \tau=e \text { in } d
$$

A definition's environment $\Gamma(d)$ comprises its binders and their reflected types:

$$
\begin{aligned}
\Gamma(\bullet) & \doteq \emptyset \\
\Gamma(\text { reflect } f: \tau=e \text { in } d) & \doteq(f, \operatorname{Reflect}(\tau, e)), \Gamma(d)
\end{aligned}
$$

A definition's substitution $\theta(d)$ maps each binder to its definition:

$$
\begin{aligned}
\theta(\bullet) & \doteq[] \\
\theta(\text { reflect } f: \tau=e \text { in } d) & \doteq[[f / \text { fix } f e], \theta(d)]
\end{aligned}
$$

"Propositions" A proposition is a type

$$
x_{1}: \tau_{1} \rightarrow \ldots \rightarrow x_{n}: \tau_{n} \rightarrow\{v: \text { Unit | prop }\}
$$

For brevity, we abbreviate propositions like the above to $\bar{x}: \bar{\tau} \rightarrow\{$ prop $\}$ and we call prop the proposition's refinement. For simplicity we assume that $\mathrm{fv}\left(\tau_{i}\right)=\emptyset$.
"Validity"
A proposition $\bar{x}: \bar{\tau} \rightarrow\{$ prop $\}$ is valid under $d$ if

$$
\forall \bar{w} \in \llbracket \bar{\tau} \rrbracket \cdot \theta(d) \cdot \operatorname{prop}[\bar{w} / \bar{x}] \hookrightarrow^{\star} \text { True }
$$

That is, the proposition is valid if its refinement evaluates to True for every (well typed) interpretation for its parameters $\bar{x}$ under $d$.
"Proofs" A binder $b$ proves a proposition $\tau$ under $d$ if

$$
\emptyset \vdash d[\operatorname{let} \operatorname{rec} x: \tau=b \text { in unit }]: \text { Unit }
$$

That is, if the binder $b$ has the proposition's type $\tau$ under the definition $d$ 's environment.
Theorem D.3. [Proofs] If b proves $\tau$ under d then $\tau$ is valid under d.
Proof. As $b$ proves $\tau$ under $d$, we have

$$
\begin{equation*}
\emptyset \vdash d[\text { let } \operatorname{rec} x: \tau=b \text { in unit }]: \text { Unit } \tag{22}
\end{equation*}
$$

By Theorem D. 2 on 22 we get

$$
\begin{equation*}
\theta(d) \in \llbracket \Gamma(d) \rrbracket \tag{23}
\end{equation*}
$$

Furthermore, by the typing rules 22 implies $\Gamma(d) \vdash b: \tau$ and hence, via Theorem D. 2

$$
\begin{equation*}
\forall \theta \in \llbracket \Gamma(d) \rrbracket \cdot \theta \cdot b \in \llbracket \theta \cdot \tau \rrbracket \tag{24}
\end{equation*}
$$

Together, 23 and 24 imply

$$
\begin{equation*}
\theta(d) \cdot b \in \llbracket \theta(d) \cdot \tau \rrbracket \tag{25}
\end{equation*}
$$

By the definition of type denotations, we have

$$
\begin{equation*}
\llbracket \theta(d) \cdot \tau \rrbracket \doteq\{f \mid \tau \text { is valid under } d\} \tag{26}
\end{equation*}
$$

By 25 , the above set is not empty, and hence $\tau$ is valid under $d$.

Example: Fibonacci is increasing In § 2 we verified that under a definition $d$ that includes fib, the term fibUp proves

$$
n: \text { Nat } \rightarrow\{\text { fib } n \leq \text { fib }(n+1)\}
$$

Thus, by Theorem D. 3 we get

$$
\forall n .0 \leq n \hookrightarrow^{\star} \text { True } \Rightarrow \text { fib } n \leq \text { fib }(n+1) \hookrightarrow^{\star} \text { True }
$$

## E PROOF OF SOUNDNESS

We prove Theorem 4.1 of $\S D$ by reduction to Soundness of $\lambda^{U}$ [56].
Theorem E.1. [Denotations] If $\Gamma \vdash p: \tau$ then $\forall \theta \in \llbracket \Gamma \rrbracket . \theta \cdot p \in \llbracket \theta \cdot \tau \rrbracket$.
Proof. We use the proof from [57] and specifically Lemma 4 that is identical to the statement we need to prove. Since the proof proceeds by induction in the type derivation, we need to ensure that all the modified rules satisfy the statement.

- T-Exact Assume $\Gamma \vdash e:\{v: B \mid\{\mid r\} \wedge v=e\}$. By inversion $\Gamma \vdash e:\{v: B \mid\{r\}\}(1)$. By (1) and IH we get $\forall \theta \in \llbracket \Gamma \rrbracket \cdot \theta \cdot e \in \llbracket \theta \cdot\{v: B \mid\{\mid r\}\} \rrbracket$. We fix a $\theta \in \llbracket \Gamma \rrbracket$ We get that if $\theta \cdot e \hookrightarrow^{\star} w$, then $\theta \cdot\{\mid r\}[v / w] \hookrightarrow^{\star}$ True. By the Definition of $=$ we get that $w=w \hookrightarrow^{\star}$ True. Since $\theta \cdot(v=e)[v / w] \hookrightarrow^{\star} w=w$, then $\theta \cdot(\{\mid r\} \wedge v=e)[v / w] \hookrightarrow^{\star}$ True. Thus $\theta \cdot e \in$ $\llbracket \theta \cdot\{v: B \mid\{\mid r\} \wedge v=e\} \rrbracket$ and since this holds for any fixed $\theta, \forall \theta \in \llbracket \Gamma \rrbracket . \theta \cdot e \in \llbracket \theta$. $\{v: B \mid\{\mid r\} \wedge v=e\} \rrbracket$.
- T-Let Assume $\Gamma \vdash$ let rec $x: \tau_{x}=e_{x}$ in $p: \tau$. By inversion $\Gamma, x: \tau_{x} \vdash e_{x}: \tau_{x}(1), \Gamma, x: \tau_{x} \vdash$ $p: \tau(2)$, and $\Gamma \vdash \tau(3)$. By $\mathrm{IH} \forall \theta \in \llbracket \Gamma, x: \tau_{x} \rrbracket \cdot \theta \cdot e_{x} \in \llbracket \theta \cdot \tau_{x} \rrbracket\left(1^{\prime}\right) \forall \theta \in \llbracket \Gamma, x: \tau_{x} \rrbracket \cdot \theta \cdot p \in \llbracket \theta \cdot \tau \rrbracket$ (2'). By ( $1^{\prime}$ ) and by the type of fix $\forall \theta \in \llbracket \Gamma, x: \tau_{x} \rrbracket . \theta \cdot$ fix $x e_{x} \in \llbracket \theta \cdot \tau_{x} \rrbracket$. By which, (2') and (3) $\forall \theta \in \llbracket \Gamma \rrbracket . \theta \cdot p\left[\right.$ fix $\left.x e_{x} / x\right] \in \llbracket \theta \cdot \tau \rrbracket$.
- T-Refl Assume $\Gamma \vdash \operatorname{reflect} f: \tau_{f}=e$ in $p: \tau$. By inversion, $\Gamma \vdash$ let rec $f: \operatorname{Reflect}\left(\tau_{f}, e\right)=$ $e$ in $p: \tau$. By IH, $\forall \theta \in \llbracket \Gamma \rrbracket . \theta \cdot$ let $\operatorname{rec} f: \operatorname{Reflect}\left(\tau_{f}, e\right)=e$ in $p \in \llbracket \theta \cdot \tau \rrbracket$. Since denotations are closed under evaluation, $\forall \theta \in \llbracket \Gamma \rrbracket \cdot \theta \cdot \operatorname{reflect} f: \operatorname{Reflect}\left(\tau_{f}, e\right)=e$ in $p \in \llbracket \theta \cdot \tau \rrbracket$.
- T-Fix In Theorem 8.3 from [57] (and using the textbook proofs from [41]) we proved that for each type $\tau$, fix $_{\tau} \in \llbracket(\tau \rightarrow \tau) \rightarrow \tau \rrbracket$.

Theorem E.2. [Preservation] If $\emptyset \vdash p: \tau$ and $p \hookrightarrow \star ~ w$ then $\emptyset \vdash w: \tau$.
Proof. In [57] proof proceeds by iterative application of Type Preservation Lemma 7. Thus, it suffices to ensure Type Preservation in $\lambda^{R}$, which it true by the following Lemma.

Lemma E.3. If $\emptyset \vdash p: \tau$ and $p \hookrightarrow p^{\prime}$ then $\emptyset \vdash p^{\prime}: \tau$.
Proof. Since Type Preservation in $\lambda^{U}$ is proved by induction on the type derivation tree, we need to ensure that all the modified rules satisfy the statement.

- T-Exact Assume $\emptyset \vdash p:\{v: B \mid\{\mid r\} \wedge v=p\}$. By inversion $\emptyset \vdash p:\{v: B \mid\{\mid r\}\}$. By IH we get $\emptyset \vdash p^{\prime}:\{v: B \mid\{\mid r\}\}$. By rule T-Exact we get $\emptyset \vdash p^{\prime}:\left\{v: B \mid\{\mid r\} \wedge v=p^{\prime}\right\}$. Since subtyping is closed under evaluation, we get $\emptyset \vdash\left\{v: B \mid\{\mid r\} \wedge v=p^{\prime}\right\} \leq\{v: B \mid\{\mid r\} \wedge v=p\}$. By rule T-Sub we get $\emptyset \vdash p^{\prime}:\{v: B \mid\{\mid r\} \wedge v=p\}$.
- T-Let Assume $\emptyset \vdash$ let rec $x: \tau_{x}=e_{x}$ in $p: \tau$. By inversion, $x: \tau_{x} \vdash e_{x}: \tau_{x}(1), x: \tau_{x} \vdash p: \tau$ (2), and $\Gamma \vdash \tau$ (3). By rule T-Fix $x: \tau_{x} \vdash$ fix $x e_{x}: \tau_{x}\left(1^{\prime}\right)$. By (1'), (2) and Lemma 6 of [57], we get $\stackrel{p}{ }\left[\right.$ fix $\left.x e_{x} / x\right]: \tau\left[\right.$ fix $\left.x e_{x} / x\right]$. By (3) $\tau\left[\right.$ fix $\left.x e_{x} / x\right] \equiv \tau$. Since $p^{\prime} \equiv p\left[\right.$ fix $\left.x e_{x} / x\right]$, we have $\emptyset \vdash p^{\prime}: \tau$.

| Predicates | p ::= | $\begin{aligned} & p \bowtie p \mid \oplus_{1} p \\ & n\|b\| x\|D\| x \bar{p} \\ & \text { if } p \text { then } p \text { else } p \end{aligned}$ |
| :---: | :---: | :---: |
| Integers | $n$ ::= | $0,-1,1$, |
| Booleans | $b$ ::= | True \| False |
| Bin Operators | $\bowtie$ : |  |
| Un Operators | $\oplus_{1} \quad::=$ | ! \| |
| Model | $\sigma \quad::=$ | $\sigma,(x: p) \mid \emptyset$ |
| Sort Arguments | $s_{a} \quad:=$ | Int \| Bool | U | Fun $s_{a} s_{a}$ |
| Sorts | $s$ ::= | $s_{a} \rightarrow s$ |

Fig. 15. Syntax of $\lambda^{S}$

- T-Refl Assume $\emptyset \vdash \operatorname{reflect} x: \tau_{x}=e_{x} \operatorname{in} p: \tau$. By double inversion, with $\tau_{x}^{\prime} \equiv \operatorname{Reflect}\left(\tau_{x}, e_{x}\right)$; $x: \tau_{x}^{\prime} \vdash e_{x}: \tau_{x}^{\prime}(1), x: \tau_{x}^{\prime} \vdash p: \tau(2)$, and $\Gamma \vdash \tau(3)$. By rule T-FIx $x: \tau_{x}^{\prime} \vdash \mathrm{fix} x e_{x}: \tau_{x}^{\prime}\left(1^{\prime}\right)$. By $\left(1^{\prime}\right)$, (2) and Lemma 6 of [57], we get $\vdash$ [fix $\left.x e_{x} / x\right]: \tau\left[\right.$ fix $\left.x e_{x} / x\right]$. By (3) $\tau\left[\right.$ fix $\left.x e_{x} / x\right] \equiv \tau$. Since $p^{\prime} \equiv p\left[\right.$ fix $\left.x e_{x} / x\right]$, we have $\emptyset \vdash p^{\prime}: \tau$.
- T-Fix This case cannot occur, as fix does not evaluate to any program.

## F ALGORITHMIC CHECKING $\lambda^{S}$ : EXTENDED VERSION

Next, we describe $\lambda^{S}$, a conservative approximation of $\lambda^{R}$ where the undecidable type subsumption rule is replaced with a decidable one, yielding an SMT-based algorithmic type system that enjoys the same soundness guarantees.

## F. 1 The SMT logic $\lambda^{S}$

Syntax: Terms \& Sorts Figure 15 summarizes the syntax of $\lambda^{S}$, the sorted (SMT-) decidable logic of quantifier-free equality, uninterpreted functions and linear arithmetic (QF-EUFLIA) [5, 36]. The terms of $\lambda^{S}$ include integers $n$, booleans $b$, variables $x$, data constructors $D$ (encoded as constants), fully applied unary $\oplus_{1}$ and binary $\bowtie$ operators, and application $x \bar{p}$ of an uninterpreted function $x$. The sorts of $\lambda^{S}$ include built-in integer Int and Bool for representing integers and booleans. The interpreted functions of $\lambda^{S}$, e.g. the logical constants $=$ and $<$, have the function sort $s \rightarrow s$. Other functional values in $\lambda^{R}$, e.g. reflected $\lambda^{R}$ functions and $\lambda$-expressions, are represented as first-order values with uninterpreted sort Fun $s s$. The universal sort $U$ represents all other values.
Semantics: Satisfaction $\boldsymbol{\&}$ Validity An assignment $\sigma$ is a mapping from variables to terms $\sigma \doteq\left\{x_{1} \mapsto p_{1}, \ldots, x_{n} \mapsto p_{n}\right\}$. We write $\sigma \mid=p$ if the assignment $\sigma$ is a model of $p$, intuitively if $\sigma p$ "is true" [36]. A predicate $p$ is satisfiable if there exists $\sigma \mid=p$. A predicate $p$ is valid if for all assignments $\sigma=p$.

## F. 2 Transforming $\lambda^{R}$ into $\lambda^{S}$

The judgment $\Gamma \vdash e \rightsquigarrow p$ states that a $\lambda^{R}$ term $e$ is transformed, under an environment $\Gamma$, into a $\lambda^{S}$ term $p$. The transformation rules are summarized in Figure 16.

## Transformation

$$
\begin{aligned}

& \rightsquigarrow \text { if app is } \mathrm{D}_{D_{1}} p \text { then } p_{1} \text { else } \ldots \text { else } p_{n}
\end{aligned}
$$

Fig. 16. Transforming $\lambda^{R}$ terms into $\lambda^{S}$.

Embedding Types We embed $\lambda^{R}$ types into $\lambda^{S}$ sorts as:

$$
\begin{array}{rlrlr}
\text { (Int) } & \doteq \text { Int } & & \| T D & \doteq \\
\text { (Bool }) & \doteq \text { Bool } & \left(x: \tau_{x} \rightarrow \tau \emptyset\right. & \doteq \text { Fun }\left(\tau_{x} \mid \backslash(\tau)\right.
\end{array}
$$

Embedding Constants Elements shared on both $\lambda^{R}$ and $\lambda^{S}$ translate to themselves. These elements include booleans ( $-\mid=B \hookrightarrow^{*}$ ool), integers $\left(-\mid=I \hookrightarrow^{*} n \mathrm{~T}\right.$ ), variables ( $-\mid=V \hookrightarrow^{*} a \mathrm{R}$ ), binary ( $\left.-\mid=B \hookrightarrow^{*} i \mathrm{~N}\right)$ and unary $\left(-\mid=U \hookrightarrow \hookrightarrow^{*} n\right)$ operators. SMT solvers do not support currying, and so in $\lambda^{S}$, all function symbols must be fully applied. Thus, we assume that all applications to primitive constants and data constructors are saturated, i.e. fully applied, e.g. by converting source level terms like (+ 1) to ( $\backslash z \rightarrow z+1$ ).
Embedding Functions As $\lambda^{S}$ is a first-order logic, we embed $\lambda$-abstraction and application using the uninterpreted functions lam and app. We embed $\lambda$-abstractions using lam as shown in rule $-\mid=F \hookrightarrow^{*} u \mathrm{~N}$. The term $\lambda x . e$ of type $\tau_{x} \rightarrow \tau$ is transformed to lams $s_{s}^{s_{x}} x p$ of sort Fun $s_{x} s$, where $s_{x}$ and $s$ are respectively $\left(\tau_{x}\right)$ and $\left.(\tau\rceil\right), l m_{s}^{s_{x}}$ is a special uninterpreted function of sort $s_{x} \rightarrow s \rightarrow$ Fun $s_{x} s$, and $x$ of sort $s_{x}$ and $r$ of sort $s$ are the embedding of the binder and body,
respectively. As lam is just an SMT-function, it does not create a binding for $x$. Instead, the binder $x$ is renamed to a fresh name pre-declared in the SMT environment.
Embedding Applications Dually, we embed applications via defunctionalization [40] using an uninterpreted apply function app as shown in rule $-\vDash A \hookrightarrow^{*} p$. The term $e e^{\prime}$, where $e$ and $e^{\prime}$ have types $\tau_{x} \rightarrow \tau$ and $\tau_{x}$, is transformed to app $s_{s}^{s_{x}} p p^{\prime}: s$ where $s$ and $s_{x}$ are respectively $(\tau)$ and $\left(\tau_{x} \mid\right.$, the app $s_{s}^{s_{x}}$ is a special uninterpreted function of sort Fun $s_{x} s \rightarrow s_{x} \rightarrow s$, and $p$ and $p^{\prime}$ are the respective translations of $e$ and $e^{\prime}$.
Embedding Data Types Rule $-\mid=D \hookrightarrow \hookrightarrow^{*} C$ translates each data constructor to a predefined $\lambda^{S}$ constant $\mathrm{s}_{D}$ of sort $(\operatorname{prim}(D))$. Let $D_{i}$ be a non-boolean data constructor such that

$$
\operatorname{prim}\left(D_{i}\right) \doteq \tau_{i, 1} \rightarrow \cdots \rightarrow \tau_{i, n} \rightarrow \tau
$$

Then the check function is $s_{D_{i}}$ has the sort Fun ( $\left.\tau\right)$ Bool, and the select function sel $l_{D_{i, j}}$ has the sort Fun $\left(\eta \tau \backslash\left(\tau_{i, j}\right)\right.$. Rule $-\vDash C \hookrightarrow^{*}$ ase translates case-expressions of $\lambda^{R}$ into nested if terms in $\lambda^{S}$, by using the check functions in the guards, and the select functions for the binders of each case. For example, following the above, the body of the list append function

```
[] ++ ys \(=y s\)
( \(x: x s\) ) ++ ys = \(x\) : ( \(x s\) ++ ys)
```

is reflected into the $\lambda^{S}$ refinement:

$$
\text { if isNil } x s \text { then } y s \text { else sel1 } x s:(\operatorname{sel2} x s++y s)
$$

We favor selectors to the axiomatic translation of HALO [60] and $\mathrm{F}^{*}$ [52] to avoid universally quantified formulas and the resulting instantiation unpredictability.

## F. 3 Correctness of Translation

Informally, the translation relation $\Gamma \vdash e \rightsquigarrow p$ is correct in the sense that if $e$ is a terminating boolean expression then $e$ reduces to True iff $p$ is SMT-satisfiable by a model that respects $\beta$-equivalence.

Definition F. 1 ( $\beta$-Model). A $\beta$-model $\sigma^{\beta}$ is an extension of a model $\sigma$ where lam and app satisfy the axioms of $\beta$-equivalence:

$$
\begin{aligned}
\forall x y e . \operatorname{lam} x e & =\operatorname{lam} y(e[x / y]) \\
\forall x e_{x} e \cdot\left(\operatorname{app}(\operatorname{lam} x e) e_{x}\right. & =e\left[x / e_{x}\right]
\end{aligned}
$$

Semantics Preservation We define the translation of a $\lambda^{R}$ term into $\lambda^{S}$ under the empty environment as $(e) \doteq p$ if $\emptyset \vdash e \rightsquigarrow p$. A lifted substitution $\theta^{\perp}$ is a set of models $\sigma$ where each "bottom" in the substitution $\theta$ is mapped to an arbitrary logical value of the respective sort [56]. We connect the semantics of $\lambda^{R}$ and translated $\lambda^{S}$ via the following theorems:

Theorem F.2. If $\Gamma \vdash e \rightsquigarrow p$, then for every $\theta \in \llbracket \Gamma \rrbracket$ and every $\sigma \in \theta^{\perp}$, if $\theta^{\perp} \cdot e \hookrightarrow{ }^{\star} v$ then $\sigma^{\beta} \mid=$ $p=(v)$.

Corollary F.3. If $\Gamma \vdash e$ : Bool, e reduces to a value and $\Gamma \vdash e \rightsquigarrow p$, then for every $\theta \in \llbracket \Gamma \rrbracket$ and every $\sigma \in \theta^{\perp}, \theta^{\perp} \cdot e \hookrightarrow^{\star}$ True iff $\sigma^{\beta} \mid=p$.

## F. 4 Decidable Type Checking

Figure 17 summarizes the modifications required to obtain decidable type checking. Namely, basic types are extended with labels that track termination and subtyping is checked via an SMT solver.
Termination Under arbitrary beta-reduction semantics (which includes lazy evaluation), soundness of refinement type checking requires checking termination, for two reasons: (1) to ensure that

$$
\text { Refined Types } \quad \tau \quad::=\left\{v: B^{[\Downarrow]}|\{ \}| \mid\right\} x: \tau \rightarrow \tau
$$

Well Formedness
$\Gamma \vdash_{S} \tau$

$$
\frac{\Gamma, v: B \vdash_{S} e: B_{0 o l}{ }^{\Downarrow}}{\Gamma \vdash_{S}\{v: B \mid e\}} \text { WF-BASE }
$$

## Subtyping

$$
\frac{\Gamma^{\prime} \doteq \Gamma, v:\left\{B^{\Downarrow} \mid e\right\} \quad \Gamma^{\prime} \vdash e^{\prime} \rightsquigarrow p^{\prime} \quad \operatorname{SmtValid}\left(\left\lfloor\Gamma^{\prime}\right\rfloor \Rightarrow p^{\prime}\right)}{\Gamma \vdash_{S}\{v: B \mid e\} \leq\left\{v: B \mid e^{\prime}\right\}} \leq- \text { BASE- } \lambda^{s}
$$

Fig. 17. Algorithmic Typing (other rules in Figs 12 and 14.)
refinements cannot diverge, and (2) to account for the environment during subtyping [56]. We use $\Downarrow$ to mark provably terminating computations, and extend the rules to use refinements to ensure that if $\Gamma \vdash_{S} e:\left\{v: B^{\Downarrow} \mid r\right\}$, then $e$ terminates [56].

Verification Conditions The verification condition $(\mathrm{VC})\lfloor\Gamma\rfloor \Rightarrow p$ is valid only if the set of values described by $\Gamma$, is subsumed by the set of values described by $p . \Gamma$ is embedded into logic by conjoining (the embeddings of) the refinements of provably terminating binders [56]:

$$
(\Gamma) \doteq \bigwedge_{x \in \Gamma}(\Gamma, x)
$$

where we embed each binder as

$$
\left(\Gamma, x \left\lvert\, \doteq \begin{cases}p & \text { if } \Gamma(x)=\left\{v: B^{\Downarrow} \mid e\right\}, \Gamma \vdash e[v / x] \rightsquigarrow p \\ \text { True } & \text { otherwise } .\end{cases}\right.\right.
$$

Subtyping via SMT Validity We make subtyping, and hence, typing decidable, by replacing the denotational base subtyping rule $\leq-$ BASE- $\lambda^{S}$ with a conservative, algorithmic version that uses an SMT solver to check the validity of the subtyping VC. We use Corollary F. 3 to prove soundness of subtyping.

$$
\text { Lemma F.4. If } \Gamma \vdash_{S}\left\{v: B \mid e_{1}\right\} \leq\left\{v: B \mid e_{2}\right\} \text { then } \Gamma \vdash\left\{v: B \mid e_{1}\right\} \leq\left\{v: B \mid e_{2}\right\}
$$

Soundness of $\lambda^{S}$ Lemma F. 4 directly implies the soundness of $\lambda^{S}$.
Theorem F. 5 (Soundness of $\lambda^{S}$ ). If $\Gamma \vdash_{S} e: \tau$ then $\Gamma \vdash e: \tau$.

## G SOUNDNESS OF ALGORITHMIC VERIFICATION

In this section we prove soundness of Algorithmic verification, by proving the theorems of § 5 by referring to the proofs in [57].

## G. 1 Transformation

Definition G. 1 (Initial Environment). We define the initial SMT environment $\Delta_{0}$ to include

| $\mathrm{s}_{c}$ | $:$ | $($ prim $(c))$ | $\forall c \in \lambda^{R}$ |
| ---: | :--- | :--- | :--- |
| $\operatorname{lam}_{s}^{s_{x}}$ | $:$ | $s_{x} \rightarrow s \rightarrow$ Fun $s_{x} s$ | $\forall s_{x}, s \in \lambda^{S}$ |
| $\operatorname{app}_{s}^{s_{x}}$ | $:$ | Fun $s_{x} s \rightarrow s_{x} \rightarrow s$ | $\forall s_{x}, s \in \lambda^{S}$ |
| $\mathrm{~s}_{D}$ | $:$ | $($ prim $(D) D$ | $\forall D \in \lambda^{R}$ |
| is $_{D}$ | $:$ | $(T \rightarrow$ BoolD | $\forall D \in \lambda^{R}$ of data type $T$ |
| $\operatorname{sel}_{D_{i}}$ | $:\left(T T \rightarrow \tau_{i} \mid\right.$ | $\forall D \in \lambda^{R}$ of data type $T$ |  |
|  |  | and $i$-th argument $\tau_{i}$ |  |
| $x_{i}^{s}$ | $: s$ | $\forall s \in \lambda^{S}$ and $1 \leq i \leq M_{\lambda}$ |  |

Where $x_{i}^{s}$ are $M_{\lambda}$ global names that only appear as lambda arguments.
We modify the $-\vDash F \hookrightarrow^{*} u$ s rule to ensure that logical abstraction is performed using the minimum globally defined lambda argument that is not already abstracted. We do so, using the helper function $\operatorname{MaxLam}(s, p)$ :

$$
\begin{aligned}
& \operatorname{MaxLam}\left(s, \operatorname{lam}_{s^{\prime}}^{s} x_{i}^{s} p\right)=\max (i, \operatorname{MaxLam}(s, p)) \\
& \operatorname{MaxLam}(s, r \bar{r})=\max (\operatorname{MaxLam}(s, p, \bar{p})) \\
& \operatorname{MaxLam}\left(s, p_{1} \bowtie p_{2}\right)=\max \left(\operatorname{MaxLam}\left(s, p_{1}, p_{2}\right)\right) \\
& \operatorname{MaxLam}\left(s, \oplus_{1} p\right)=\operatorname{MaxLam}(s, p) \\
& \operatorname{MaxLam}\left(s, \text { if } p \text { then } p_{1} \text { else } p_{2}\right)=\max \left(\operatorname{MaxLam}\left(s, p, p_{1}, p_{2}\right)\right) \\
& \operatorname{MaxLam}(s, p)=0
\end{aligned}
$$

Lemma G. 2 (Type Transformation). If $\Gamma \vdash e \rightsquigarrow p$, and $\Gamma \vdash e: \tau$, then $\Delta_{0},(\Gamma) \vdash_{s} p:(\tau)$.
Proof. We proceed by induction on the translation

- $-\mid=B \hookrightarrow{ }^{*}$ ool: Since (Bool) $=$ Bool, If $\Gamma \vdash b$ : Bool, then $\Delta_{0},(\Gamma) \vdash s b:($ Bool $)$.
-     - $\mid=I \hookrightarrow^{*} n$ T: Since (Int) $=$ Int, If $\Gamma \vdash n:$ Int, then $\Delta_{0},(\Gamma \mid) \vdash_{S} n:($ Int $)$ ).
-     - $=U \hookrightarrow{ }^{*} n$ : Since $\Gamma \vdash!e: \tau$, then it should be $\Gamma \vdash e$ : Bool and $\tau \equiv$ Bool. By IH, $\Delta_{0},(\Gamma) \vdash_{s} p:\left(\right.$ Bool ), thus $\Delta_{0},(\Gamma) \vdash_{s}!p:($ Bool $)$.
-     - $=B \hookrightarrow{ }^{*}{ }^{*}$ in Assume $\Gamma \vdash e_{1} \bowtie e_{2} \rightsquigarrow p_{1} \bowtie p_{2}$. By inversion $\Gamma \vdash e_{1} \rightsquigarrow p_{1}$, and $\Gamma \vdash e_{2} \rightsquigarrow p_{2}$. Since $\Gamma \vdash e_{1} \bowtie e_{2}: \tau$, then $\Gamma \vdash e_{1}: \tau_{1}$ and $\Gamma \vdash e_{1}: \tau_{2}$. By $\mathrm{IH}, \Delta_{0},(\Gamma) \vdash_{s} p_{1}:\left(\tau_{1}\right)$ and $\Delta_{0},(\Gamma) \vdash_{s} p_{2}:\left(\tau_{2}\right)$. We split cases on $\bowtie$
- If $\bowtie \equiv=$, then $\tau_{1}=\tau_{2}$, thus $\left(\tau_{1}\right)=\left(\tau_{2}\right)$ and $(\tau)=\tau=$ Bool.
- If $\bowtie \equiv<$, then $\tau_{1}=\tau_{2}=$ Int, thus $\left(\tau_{1} \mid\right)=\left(\tau_{2}\right)=$ Int and $(\tau)=\tau=$ Bool.
- If $\bowtie \equiv \wedge$, then $\tau_{1}=\tau_{2}=$ Bool, thus $\left(\tau_{1} \mid\right)=\left(\tau \tau_{2}\right)=$ Bool and $(\tau)=\tau=$ Bool.
- If $\bowtie \equiv+$ or $\bowtie \equiv-$, then $\tau_{1}=\tau_{2}=$ Int, thus $\left.\left(\tau_{1}\right\rangle=\ \tau_{2}\right\rangle=$ Int and $(\tau)=\tau=$ Int.
-     - $=V \hookrightarrow^{*}$ aR: Assume $\Gamma \vdash x \rightsquigarrow x$ Then $\Gamma \vdash x: \Gamma(x)$ and $\Delta_{0},(\Gamma) \vdash_{s} x:(\Gamma\rangle(x)$. But by definition $((\Gamma))(x)=(\Gamma(x))$.
-     - $=O \hookrightarrow^{*} p$ : Assume $\Gamma \vdash c \rightsquigarrow \mathrm{~s}_{c}$ Also, $\Gamma \vdash c: \operatorname{prim}(c)$ and $\Delta_{0},(\Gamma) \vdash_{s} \mathrm{~s}_{c}: \Delta_{0}\left(\mathrm{~s}_{c}\right)$. But by Definition G. $1 \Delta_{0}\left(\mathrm{~s}_{c}\right)=(\operatorname{prim}(c))$.
-     - $=D \hookrightarrow{ }^{*} C$ : Assume $\Gamma \vdash D \rightsquigarrow \mathrm{~s}_{D}$ Also, $\Gamma \vdash D: \operatorname{prim}(D)$ and $\Delta_{0},(\Gamma) \vdash \mathrm{s}_{\mathrm{S}}: \Delta_{0}\left(\mathrm{~s}_{D}\right)$. But by Definition G. $1 \Delta_{0}\left(s_{D}\right)=(\operatorname{prim}(c))$.
-     - $=F \hookrightarrow^{*} u \mathrm{~N}$ : Assume $\Gamma \vdash \lambda x$. $e \rightsquigarrow \operatorname{lam}_{(\{\tau)}^{\left(\left|\tau_{x}\right|\right)} x_{i}^{\left(\mid \tau_{x}\right)} p$. By inversion $i \leq M_{\lambda} \Gamma, x_{i}^{\left(\left|\tau_{x}\right|\right)}: \tau_{x} \vdash$ $e\left[x / x_{i}^{\left(\| \tau_{x}\right)}\right] \rightsquigarrow p$, and $\Gamma \vdash(\lambda x . e):\left(x: \tau_{x} \rightarrow \tau\right)$. By the Definition G. 1 on lam, $x_{i}^{s}$ and induction, we get $\Delta_{0},(\Gamma \mid) \vdash_{S} \operatorname{lam}_{(\{\tau)}^{\left(\mid \tau_{x}\right)} x_{i}^{\left(\mid \tau_{x}\right)} p$ :Fun $\left.\left(\tau_{x}\right) \backslash \tau \tau\right)$. By the definition of the type embeddings we have $\left(x \rightarrow \tau_{x} \tau\right) \doteq$ Fun $\left(\tau_{x}\right)(\tau)$.
-     - $=A \hookrightarrow * ~ p$ p: Assume $\Gamma \vdash e e^{\prime} \rightsquigarrow \operatorname{app}_{(\tau \tau)}^{\left(\tau_{x}\right)} p p^{\prime}$. By inversion, $\Gamma \vdash e^{\prime} \rightsquigarrow p^{\prime}, \Gamma \vdash e \rightsquigarrow p$, $\Gamma \vdash e: x: \tau_{x} \rightarrow \tau$. By IH and the type of app we get that $\Delta_{0},(\mid \Gamma) \vdash s \operatorname{app}_{(\mid \tau)}^{\left(\tau_{x}\right)} p p^{\prime}:(\tau)$.
-     - $=I \hookrightarrow^{*} f$ : Assume $\Gamma$ ト case $x=e$ of $\left\{\right.$ True $\rightarrow e_{1}$; False $\left.\rightarrow e_{2}\right\} \rightsquigarrow$ if $p$ then $p_{1}$ else $p_{2}$ Since $\Gamma \vdash$ case $x=e$ of $\left\{\right.$ True $\rightarrow e_{1}$; False $\left.\rightarrow e_{2}\right\}: \tau$, then $\Gamma \vdash e:$ Bool, $\Gamma \vdash e_{1}: \tau$, and $\Gamma \vdash e_{2}: \tau$. By inversion and $\mathrm{IH}, \Delta_{0},(\Gamma) \vdash s p: B o o l, \Delta_{0},(\Gamma) \vdash s p_{1}:(\tau \tau)$, and $\Delta_{0},(\Gamma) \vdash s p_{2}:(\| \tau)$. Thus, $\Delta_{0},(\Gamma) \vdash_{s}$ if $p$ then $p_{1}$ else $p_{2}:(\tau)$.
-     - $=C \hookrightarrow{ }^{*}$ ase: Assume $\Gamma$ ト case $x=e$ of $\left\{D_{i} \overline{y_{i}} \rightarrow e_{i}\right\} \rightsquigarrow$ if is $D_{D_{1}} p$ then $p_{1}$ else $\ldots$ else $p_{n}$ and $\Gamma \vdash$ case $x=e$ of $\left\{D_{i} \overline{y_{i}} \rightarrow e_{i}\right\}: \tau$. By inversion we get $\Gamma \vdash e \rightsquigarrow p$ and $\Gamma \vdash$ $e_{i}\left[\overline{y_{i}} / \overline{\operatorname{sel}_{D_{i}} x}\right][x / e] \rightsquigarrow p_{i}$. By IH and the Definition G. 1 on the checkers and selectors, we get $\Delta_{0},(\Gamma) \vdash_{s}$ if is $s_{D_{1}} p$ then $p_{1}$ else $\ldots$ else $p_{n}:(\tau \tau)$.

Theorem G.3. If $\Gamma \vdash e \rightsquigarrow p$, then for every substitution $\theta \in \llbracket \Gamma \rrbracket$ and every model $\sigma \in \llbracket \theta^{\perp} \rrbracket$, if $\theta^{\perp} \cdot e \hookrightarrow^{\star} v$ then $\sigma^{\beta}=p=\llbracket v \rrbracket$.

Proof. We proceed using the notion of tracking substitutions from Figure 8 of [57]. Since $\theta^{\perp} \cdot e \hookrightarrow^{\star} v$, there exists a sequence of evaluations via tracked substitutions,

$$
\left\langle\theta_{1}^{\perp} ; e_{1}\right\rangle \hookrightarrow \ldots\left\langle\theta_{i}^{\perp} ; e_{i}\right\rangle \cdots \hookrightarrow\left\langle\theta_{n}^{\perp} ; e_{n}\right\rangle
$$

with $\theta_{1}^{\perp} \equiv \theta^{\perp}, e_{1} \equiv e$, and $e_{n} \equiv v$. Moreover, each $e_{i+1}$ is well formed under $\Gamma$, thus it has a translation $\Gamma \vdash e_{i+1} \rightsquigarrow p_{i+1}$. Thus we can iteratively apply Lemma G. $5 n-1$ times and since $v$ is a value the extra variables in $\theta_{n}^{\perp}$ are irrelevant, thus we get the required $\sigma^{\beta} \mid=p=\llbracket v \rrbracket$.

For Boolean expressions we specialize the above to
Corollary G.4. If $\Gamma \vdash e:$ Bool ${ }^{\downarrow}$ and $\Gamma \vdash e \rightsquigarrow p$, then for every substitution $\theta \in \llbracket \Gamma \rrbracket$ and every model $\sigma \in \llbracket \theta^{\perp} \rrbracket, \theta^{\perp} \cdot e \hookrightarrow \star$ True $\Longleftrightarrow \sigma^{\beta} \vDash p$
Proof. We prove the left and right implication separately:

- $\Rightarrow$ By direct application of Theorem G. 3 for $v \equiv$ True.
$\bullet \Leftarrow$ Since $e$ is terminating, $\theta^{\perp} \cdot e \hookrightarrow^{\star} v$. with either $v \equiv$ True or $v \equiv$ False. Assume $v \equiv \mathrm{False}$, then by Theorem G.3, $\sigma^{\beta} \mid=!p$, which is a contradiction. Thus, $v \equiv$ True.

Lemma G. 5 (Equivalence Preservation). If $\Gamma \vdash e \rightsquigarrow p$, then for every substitution $\theta \in \llbracket \Gamma \rrbracket$ and every model $\sigma \in \llbracket \theta^{\perp} \rrbracket$, if $\left\langle\theta^{\perp} ; e\right\rangle \hookrightarrow\left\langle\theta_{2}^{\perp} ; e_{2}\right\rangle$ and for $\Gamma \subseteq \Gamma_{2}$ so that $\theta_{2}^{\perp} \in \llbracket \Gamma_{2} \rrbracket$ and $\sigma_{2}^{\beta} \in \llbracket \theta_{2}^{\perp} \rrbracket$, $\Gamma_{2}+e_{2} \rightsquigarrow p_{2}$ then $\sigma^{\beta} \cup\left(\sigma_{2}^{\beta} \backslash \sigma^{\beta}\right) \vDash p=p_{2}$.

Proof. We proceed by case analysis on the derivation $\left\langle\theta^{\perp} ; e\right\rangle \hookrightarrow\left\langle\theta_{2}^{\perp} ; e_{2}\right\rangle$.

- Assume $\left\langle\theta^{\perp} ; e_{1} e_{2}\right\rangle \hookrightarrow\left\langle\theta_{2}^{\perp} ; e_{1}^{\prime} e_{2}\right\rangle$. By inversion $\left\langle\theta^{\perp} ; e_{1}\right\rangle \hookrightarrow\left\langle\theta_{2}^{\perp} ; e_{1}^{\prime}\right\rangle$. Assume $\Gamma \vdash e_{1} \rightsquigarrow p_{1}$, $\Gamma \vdash e_{2} \rightsquigarrow p_{2}, \Gamma_{2} \vdash e_{1}^{\prime} \rightsquigarrow p_{1}^{\prime}$. By IH $\sigma^{\beta} \cup\left(\sigma_{2}^{\beta} \backslash \sigma^{\beta}\right) \mid=p_{1}=p_{1}^{\prime}$, thus $\sigma^{\beta} \cup\left(\sigma_{2}^{\beta} \backslash \sigma^{\beta}\right) \vDash$ app $p_{1} p_{2}=$ app $p_{1}^{\prime} p_{2}$.
- Assume $\left\langle\theta^{\perp} ; c e\right\rangle \hookrightarrow\left\langle\theta_{2}^{\perp} ; c e^{\prime}\right\rangle$. By inversion $\left\langle\theta^{\perp} ; e\right\rangle \hookrightarrow\left\langle\theta_{2}^{\perp} ; e^{\prime}\right\rangle$. Assume $\Gamma \vdash e \rightsquigarrow p$, $\Gamma \vdash e^{\prime} \rightsquigarrow p^{\prime}$. By IH $\sigma^{\beta} \cup\left(\sigma_{2}^{\beta} \backslash \sigma^{\beta}\right) \mid=p=p^{\prime}$, thus $\sigma^{\beta} \cup\left(\sigma_{2}^{\beta} \backslash \sigma^{\beta}\right) \mid=$ app $c p=$ app $c p^{\prime}$.
- Assume $\left\langle\theta^{\perp}\right.$; case $x=e$ of $\left.\left\{D_{i} \overline{y_{i}} \rightarrow e_{i}\right\}\right\rangle \hookrightarrow\left\langle\theta_{2}^{\perp}\right.$; case $x=e^{\prime}$ of $\left.\left\{D_{i} \overline{y_{i}} \rightarrow e_{i}\right\}\right\rangle$. By inversion $\left\langle\theta^{\perp} ; e\right\rangle \hookrightarrow\left\langle\theta_{2}^{\perp} ; e^{\prime}\right\rangle$. Assume $\Gamma \vdash e \rightsquigarrow p, \Gamma \vdash e^{\prime} \rightsquigarrow p^{\prime}$. $\Gamma \vdash e_{i}\left[\overline{y_{i}} / \overline{\operatorname{sel}_{D_{i}} x}\right][x / e] \rightsquigarrow p_{i}$. By IH $\sigma^{\beta} \cup\left(\sigma_{2}^{\beta} \backslash \sigma^{\beta}\right) \mid=p=p^{\prime}$, thus $\sigma^{\beta} \cup\left(\sigma_{2}^{\beta} \backslash \sigma^{\beta}\right) \mid=$ if is D $_{D_{1}} p$ then $p_{1}$ else $\ldots$ else $p_{n}(\tau)$ $=$ if is $D_{D_{1}} p^{\prime}$ then $p_{1}$ else $\ldots$ else $p_{n}(\tau)$.
- Assume $\left\langle\theta^{\perp} ; D \overline{e_{i}}\right.$ e $\left.\overline{e_{j}}\right\rangle \hookrightarrow\left\langle\theta_{2}^{\perp} ; D \overline{e_{i}} e^{\prime} \overline{e_{j}}\right\rangle$. By inversion $\left\langle\theta^{\perp} ; e\right\rangle \hookrightarrow\left\langle\theta_{2}^{\perp} ; e^{\prime}\right\rangle$. Assume $\Gamma \vdash$ $e \rightsquigarrow p, \Gamma \vdash e_{i} \rightsquigarrow p_{i}, \Gamma \vdash e^{\prime} \rightsquigarrow p^{\prime}$. By IH $\sigma^{\beta} \cup\left(\sigma_{2}^{\beta} \backslash \sigma^{\beta}\right) \mid=p=p^{\prime}$, thus $\sigma^{\beta} \cup\left(\sigma_{2}^{\beta} \backslash \sigma^{\beta}\right) \mid=$ $\operatorname{app} D \overline{p_{i}} p \overline{p_{j}}=\operatorname{app} D \overline{p_{i}} p^{\prime} \overline{p_{j}}$.
- Assume $\left\langle\theta^{\perp} ; c w\right\rangle \hookrightarrow\left\langle\theta^{\perp} ; \delta(c, w)\right\rangle$. By the definition of the syntax, $c w$ is a fully applied logical operator, thus $\sigma^{\beta} \cup\left(\sigma_{2}^{\beta} \backslash \sigma^{\beta}\right) \vDash c w=\llbracket \delta(c, w) \rrbracket$
- Assume $\left\langle\theta^{\perp} ;(\lambda x . e) e_{x}\right\rangle \hookrightarrow\left\langle\theta^{\perp} ; e\left[x / e_{x}\right]\right\rangle$. Assume $\Gamma \vdash e \rightsquigarrow p, \Gamma \vdash e_{x} \rightsquigarrow p_{x}$. Since $\sigma^{\beta}$ is defined to satisfy the $\beta$-reduction axiom, $\sigma^{\beta} \cup\left(\sigma_{2}^{\beta} \backslash \sigma^{\beta}\right) \mid=\operatorname{app}(\operatorname{lam} x e) p_{x}=p\left[x / p_{x}\right]$.
- Assume $\left\langle\theta^{\perp}\right.$; case $x=D_{j} \bar{e}$ of $\left.\left\{D_{i} \overline{y_{i}} \rightarrow e_{i}\right\}\right\rangle \hookrightarrow\left\langle\theta^{\perp} ; e_{j}\left[x / D_{j} \bar{e}\right]\left[y_{i} / \bar{e}\right]\right\rangle$. Also, let $\Gamma \vdash e \rightsquigarrow p$, $\Gamma \vdash e_{i}\left[x / D_{j} \bar{e}\right]\left[y_{i} / \overline{e_{i}}\right] \rightsquigarrow p_{i}$. By the axiomatic behavior of the measure selector is ${ }_{D_{j} \bar{p}}$, we get $\sigma^{\beta} \mid=$ is $D_{D_{j}} \bar{p}$. Thus, $\sigma^{\beta}$ if is $s_{D_{1}} p$ then $p_{1}$ else $\ldots$ else $p_{n}=p_{j}$.
- Assume $\left\langle\left(x, e_{x}\right) \theta^{\perp} ; x\right\rangle \hookrightarrow\left\langle\left(x, e_{x}^{\prime}\right) \theta_{2}^{\perp} ; x\right\rangle$. By inversion $\left\langle\theta^{\perp} ; e_{x}\right\rangle \hookrightarrow\left\langle\theta_{2}^{\perp} ; e_{x}^{\prime}\right\rangle$. By identity of equality, $\left(x, p_{x}\right) \sigma^{\beta} \cup\left(\sigma_{2}^{\beta} \backslash \sigma^{\beta}\right) \mid=x=x$.
- Assume $\left\langle\left(y, e_{y}\right) \theta^{\perp} ; x\right\rangle \hookrightarrow\left\langle\left(y, e_{y}\right) \theta_{2}^{\perp} ; e_{x}\right\rangle$. By inversion $\left\langle\theta^{\perp} ; x\right\rangle \hookrightarrow\left\langle\theta_{2}^{\perp} ; e_{x}\right\rangle$. Assume $\Gamma \vdash e_{x} \rightsquigarrow$ $p_{x}$. By IH $\sigma^{\beta} \cup\left(\sigma_{2}^{\beta} \backslash \sigma^{\beta}\right) \mid=x=p_{x}$. Thus $\left(y, p_{y}\right) \sigma^{\beta} \cup\left(\sigma_{2}^{\beta} \backslash \sigma^{\beta}\right) \mid=x=p_{x}$.
- Assume $\left\langle(x, w) \theta^{\perp} ; x\right\rangle \hookrightarrow\left\langle(x, w) \theta^{\perp} ; w\right\rangle$. Thus $(x, \llbracket w \rrbracket) \sigma^{\beta} \mid=x=\llbracket w \rrbracket$.
- Assume $\left\langle(x, D \bar{y}) \theta^{\perp} ; x\right\rangle \hookrightarrow\left\langle(x, D \bar{y}) \theta^{\perp} ; D \bar{y}\right\rangle$. Thus $(x, \operatorname{app} D \bar{y}) \sigma^{\beta} \mid=x=\operatorname{app} D \bar{y}$.
- Assume $\left\langle(x, D \bar{e}) \theta^{\perp} ; x\right\rangle \hookrightarrow\left\langle(x, D \bar{y}), \overline{\left(y_{i}, e_{i}\right)} \theta^{\perp} ; D \bar{y}\right\rangle$. Assume $\Gamma \vdash e_{i} \rightsquigarrow p_{i}$. Thus $(x, \operatorname{app} D \bar{y}), \overline{\left(y_{i}, p_{i}\right)} \sigma^{\beta} \mid=$ $x=\operatorname{app} D \bar{y}$.

## G. 2 Soundness of Approximation

Theorem G. 6 (Soundness of Algorithmic). If $\Gamma \vdash s e: \tau$ then $\Gamma \vdash e: \tau$.
Proof. To prove soundness it suffices to prove that subtyping is appropriately approximated, as stated by the following lemma.

Lemma G.7. If $\Gamma \vdash_{s}\left\{v: B \mid e_{1}\right\} \leq\left\{v: B \mid e_{2}\right\}$ then $\Gamma \vdash\left\{v: B \mid e_{1}\right\} \leq\left\{v: B \mid e_{2}\right\}$.
Proof. By rule $\leq-$ Base- $\lambda^{S}$, we need to show that $\forall \theta \in \llbracket \Gamma \rrbracket \cdot \llbracket \theta \cdot\left\{v: B \mid e_{1}\right\} \rrbracket \subseteq \llbracket \theta \cdot\left\{v: B \mid e_{2}\right\} \rrbracket$. We fix a $\theta \in \llbracket \Gamma \rrbracket$. and get that forall bindings $\left(x_{i}:\left\{v: B^{\downarrow} \mid e_{i}\right\}\right) \in \Gamma, \theta \cdot e_{i}\left[v / x_{i}\right] \hookrightarrow^{\star}$ True.

Then need to show that for each $e$, if $e \in \llbracket \theta \cdot\left\{v: B \mid e_{1}\right\} \rrbracket$, then $e \in \llbracket \theta \cdot\left\{v: B \mid e_{2}\right\} \rrbracket$.
If $e$ diverges then the statement trivially holds. Assume $e \hookrightarrow^{\star} w$. We need to show that if $\theta \cdot e_{1}[v / w] \hookrightarrow^{\star}$ True then $\theta \cdot e_{2}[v / w] \hookrightarrow^{\star}$ True.
Let $\theta^{\perp}$ the lifted substitution that satisfies the above. Then by Lemma G. 4 for each model $\sigma^{\beta} \in \llbracket \theta^{\perp} \rrbracket, \sigma^{\beta} \mid=p_{i}$, and $\sigma^{\beta} \vDash q_{1}$ for $\Gamma \vdash e_{i}\left[v / x_{i}\right] \rightsquigarrow p_{i} \Gamma \vdash e_{i}[v / w] \rightsquigarrow q_{i}$. Since $\Gamma \vdash s\{v: B \mid$ $\left.e_{1}\right\} \leq\left\{v: B \mid e_{2}\right\}$ we get

$$
\bigwedge_{i} p_{i} \Rightarrow q_{1} \Rightarrow q_{2}
$$

thus $\sigma^{\beta} \mid=q_{2}$. By Theorem F. 3 we get $\theta \cdot e_{2}[v / w] \hookrightarrow \hookrightarrow^{\star}$ True.

## H REASONING ABOUT LAMBDAS

Encoding of $\lambda$-abstractions and applications via uninterpreted functions, while sound, is imprecise as it makes it hard to prove theorems that require $\alpha$ - and $\beta$-equivalence or extensional equality. Using the universally quantified $\alpha$ - and $\beta$ - equivalence axioms would let the type checker accept more programs, but would render validity, and hence, type checking undecidable. Next, we identify a middle ground by describing an not provably complete, but sound and decidable approach to increase the precision of type checking by strengthening the VCs with instances of the $\alpha$ - and $\beta$ - equivalence axioms $\S \mathrm{H} .1$ and by introducing a combinator for safely asserting extensional equality § H.2. In the sequel, we omit app when it is clear from the context.

## H. 1 Equivalence

As soundness relies on satisfiability under a $\sigma^{\beta}$ (see Definition F.1), we can safely instantiate the axioms of $\alpha$ - and $\beta$-equivalence on any set of terms of our choosing and still preserve soundness (Theorem 5.2). That is, instead of checking the validity of a VC $p \Rightarrow q$, we check the validity of a strengthened $V C, a \Rightarrow p \Rightarrow q$, where $a$ is a (finite) conjunction of equivalence instances derived from $p$ and $q$, as discussed below.
Representation Invariant The lambda binders, for each SMT sort, are drawn from a pool of names $x_{i}$ where the index $i=1,2, \ldots$. When representing $\lambda$ terms we enforce a normalization invariant that for each lambda term $\operatorname{lam} x_{i} e$, the index $i$ is greater than any lambda argument appearing in $e$.
$\alpha$-instances For each syntactic term lam $x_{i} e$ and $\lambda$-binder $x_{j}$ such that $i<j$ appearing in the VC, we generate an $\alpha$-equivalence instance predicate (or $\alpha$-instance):

$$
\operatorname{lam} x_{i} e=\operatorname{lam} x_{j} e\left[x_{i} / x_{j}\right]
$$

The conjunction of $\alpha$-instances can be more precise than De Bruijn representation, as they let the SMT solver deduce more equalities via congruence. For example, this VC is needed to prove the applicative laws for Reader:

$$
d=\operatorname{lam} x_{1}\left(x x_{1}\right) \quad \Rightarrow \quad \operatorname{lam} x_{2}\left(\left(\operatorname{lam} x_{1}\left(x x_{1}\right)\right) x_{2}\right)=\operatorname{lam} x_{1}\left(d x_{1}\right)
$$

The $\alpha$ instance lam $x_{1}\left(d x_{1}\right)=\operatorname{lam} x_{2}\left(d x_{2}\right)$ derived from the VC's hypothesis, combined with congruence immediately yields the VC's consequence.
$\beta$-instances For each syntactic term app (lam $x e) e_{x}$, with $e_{x}$ not containing any $\lambda$-abstractions, appearing in the VC , we generate a $\beta$-equivalence instance predicate (or $\beta$-instance):

$$
\operatorname{app}\left(\operatorname{lam} x_{i} e\right) e_{x}=e\left[e_{x} / x_{i}\right], \text { s.t. } e_{x} \text { is } \lambda \text {-free }
$$

The $\lambda$-free restriction is a simple way to enforce that the reduced term $e\left[e^{\prime} / x_{i}\right]$ enjoys the representation invariant. For example, consider the following VC needed to prove that the bind operator for lists satisfies the monadic associativity law.

$$
(f x \gg=g)=\operatorname{app}(\operatorname{lam} y(f y \gg=g)) x
$$

The right-hand side of the above VC generates a $\beta$-instance that corresponds directly to the equality, allowing the SMT solver to prove the (strengthened) VC.
Normalization The combination of $\alpha$ - and $\beta$-instances is often required to discharge proof obligations. For example, when proving that the bind operator for the Reader monad is associative, we need to prove the VC :

$$
\operatorname{lam} x_{2}\left(\operatorname{lam} x_{1} w\right)=\operatorname{lam} x_{3}\left(\operatorname{app}\left(\operatorname{lam} x_{2}\left(\operatorname{lam} x_{1} w\right)\right) w\right)
$$

The SMT solver proves the VC via the equalities corresponding to an $\alpha$ and then $\beta$-instance:

$$
\operatorname{lam} x_{2}\left(\operatorname{lam} x_{1} w\right)={ }_{\alpha} \operatorname{lam} x_{3}\left(\operatorname{lam} x_{1} w\right)={ }_{\beta} \operatorname{lam} x_{3}\left(\operatorname{app}\left(\operatorname{lam} x_{2}\left(\operatorname{lam} x_{1} w\right)\right) w\right)
$$

## H. 2 Extensionality

Often, we need to prove that two functions are equal, given the definitions of reflected binders. Consider

```
reflect id
id x = x
```

Liquid Haskell accepts the proof that id $x=x$ for all $x$ :

```
id_x_eq_x :: x:a }->\mathrm{ {id x = x}
id_x_eq_x = \x }->\mathrm{ id x =. x ** QED
```

as "calling" id unfolds its definition, completing the proof. However, consider this $\eta$-expanded variant of the above proposition:

```
type Id_eq_id = {(\x }->\mathrm{ id x ) = (\y }->\textrm{y})
```

Liquid Haskell rejects the proof:

```
fails :: Id_eq_id
fails = (\x }->\mathrm{ id x) =. (\y }->\mathrm{ y) ** QED
```

The invocation of id unfolds the definition, but the resulting equality refinement $\{i d x=x\}$ is trapped under the $\lambda$-abstraction. That is, the equality is absent from the typing environment at the top level, where the left-hand side term is compared to $\backslash y \rightarrow y$. Note that the above equality requires the definition of id and hence is outside the scope of purely the $\alpha$ - and $\beta$-instances.
An Exensionality Operator To allow function equality via extensionality, we provide the user with a (family of) function comparison operator(s) that transform an explanation p which is a proof that $f x=g \times$ for every argument $x$, into a proof that $f=g$.

$$
=\star:: f:(a \rightarrow b) \rightarrow g:(a \rightarrow b) \rightarrow \exp :(x: a \rightarrow\{f x=g x\}) \rightarrow\{f=g\}
$$

Of course, =* cannot be implemented; its type is assumed. We can use =* to prove Id_eq_id by providing a suitable explanation:

```
pf_id_id :: Id_eq_id
pf_id_id = (\y -> y) =* (\x -> id x) \because expl ** QED where expl = (\x }->\mathrm{ id x =. x
** QED)
```

The explanation is the second argument to $\because$ which has the following type that syntactically fires $\beta$-instances:

$$
x: a \rightarrow\{(\backslash x \rightarrow \text { id } x) x=((\backslash x \rightarrow x) x\}
$$

## I IMPLEMENTATION

Refinement reflection and PLE are implemented in Liquid Haskell. The implementation can be found in the Liquid Haskell GitHub repository, all the benchmarks of § 2 and $\S 7$ are included in the nople and ple test directories. The benchmarks for deterministic parallelism can be found at class-laws and detpar-laws.

Next, we describe the file ProofCombinators.hs, the library of proof combinators used by our benchmarks and discuss known limitations of our implementation.

## I. 1 ProofCombinators: The Proof Combinators Library

In this section we present ProofCombinators, a Haskell library used to structure proof terms. ProofCombinators is inspired by Equational Reasoning Data Types in Adga [34], providing operators to construct proofs for equality and linear arithmetic in Haskell. The constructed proofs are checked by an SMT-solver via Liquid Types.
Proof terms are defined in ProofCombinators as a type alias for unit, a data type that curries no run-time information

```
type Proof = ()
```

Proof types are refined to express theorems about program functions. For example, the following Proof type expresses that fib $2==1$
fib2 : : () $\rightarrow\{v:$ Proof | fib $2==1\}$
We simplify the above type by omitting the irrelevant basic type Proof and variable $v$

```
fib2 :: () }->{{fib 2 == 1
```

ProofCombinators provides primitives to construct proof terms by casting expressions to proofs. To resemble mathematical proofs, we make this casting post-fix. We write $p$ *** QED to cast $p$ to a proof term, by defining two operators QED and $* * *$ as

```
data QED = QED
(***) :: a }->\mathrm{ QED }->\mathrm{ Proof
_ *** _ = ()
```

Proof construction. To construct proof terms, ProofCombinators provides a proof constructor $\odot$. for logical operators of the theory of linear arithmetic and equality: $\{=, \neq, \leq,<, \geq,>\} \in \odot . \odot . \mathrm{x}$ y ensures that $x \odot y$ holds, and returns $x$

```
\odot.:: x:a -> y:{a| x \odot y} -> {v:a| v==x}
\odot. x _ = x
-- for example
==.:: x:a -> y:{a| x==y} -> {v:a| v==x}
```

For instance, using ==. we construct a proof, in terms of Haskell code, that fib $2==1$ :

```
fib2 _
    = fib 2
    ==. fib 1 + fib 0
    ==. 1
    *** QED
```

Reusing proofs: Proofs as optional arguments. Often, proofs require reusing existing proof terms. For example, to prove fib $3==2$ we can reuse the above fib2 proof. We extend the proof combinators, to receive an optional third argument of Proof type.

```
\(\odot .: x: x \rightarrow y: a \rightarrow\{x \odot y\} \rightarrow\{v: a \mid v==x\}\)
๑. \(x_{\text {_ }}=x\)
```

$\odot . \mathrm{x}$ y p returns x while the third argument p explicitly proves $x \odot y$.
Optional Arguments. The proof term argument is optional. To implement optional arguments in Haskell we use the standard technique where for each operator $\odot$ we define a type class $0 p t \odot$ that
takes as input two expressions a and returns a result $r$, which will be instantiated with either the result value $r:=a$ or a function form a proof to the result $r:=\operatorname{Proof} \rightarrow a$.

```
class Opt\odot a r where
    (\odot.) :: a }->\textrm{a}->\textrm{r
```

When no explicit proof argument is required, the result type is just an $y$ : a that curries the proof

```
x \odot y
    instance Opt\odot a a where
    (\odot.) :: x:a->y:{a| x \odot y} }->{v:a | v==x }
    (\odot.) x _ = x
```

Note that Haskell's type inference [49] requires both type class parameters a and $r$ to be constrainted at class instance matching time. In most our examples, the result type parameter $r$ is not constrained at instance matching time, thus due to the Open World Assumption the matching instance could not be determined. To address the above, we used another common Haskell trick, of generalizing the instance to type arguments $a$ and $b$ and then constraint $a$ and $b$ to be equal $a \sim b$. This generalization allows the instance to always match and imposed the equality constraint after matching.

```
instance (a~b) =Opt\odot a b where
(\odot.) :: x:a->y:{x \odot y} }->{v:b | v==x }
(\odot.) x _ = x
```

To explicitly provide a proof argument, the result type $r$ is instantiated to $r:=$ Proof $\rightarrow$ a. For the same instance matching restrictions as above, the type is further generalized to return some $b$ that is constraint to be equal to a.

```
instance (a~b) =Opt\odot a (Proof }->\textrm{b}\mathrm{ ) where
(\odot.) :: x:a->y:a->{x \odot y} }->{v:b | v==x 
(\odot.) x _ _ = x
```

As a concrete example, we define the equality operator $==$. via the type class OptEq as

```
class OptEq a r where
    (==.):: a }->\textrm{a}->\textrm{r
instance (a~b) }=>\mathrm{ OptEq a b where
    (==.) ): :x:a->y:{a|x==y}->{v:b|v== x}
    (==.) x _ = x
instance (a~b) =0ptEq a (Proof }->\textrm{b}\mathrm{ ) where
    (==.) ): x:a->y:a->{x== y} }->{v:b|v==x
    (==.) x _ _ = x
```

Explanation Operator. The "explanation operator" (?), or ( $\because$ ), is used to better structure the proofs. (?) is an infix operator with same fixity as (๑.) that allows for the equivalence $\mathrm{x} \odot . \mathrm{y}$ ? $\mathrm{p}=(\odot) \times \mathrm{y} \mathrm{p}$
(?) :: (Proof $\rightarrow$ a) $\rightarrow$ Proof $\rightarrow a$
f ? $y=f y$
Putting it all together Using the above operators, we prove that fib $3==2$, reusing the previous proof of fib $2==1$, in a Haskell term that resembles mathematical proofs

```
fib3 :: () }->\mathrm{ {fib 3 == 2}
fib3 -
    = fib 3
    ==. fib 2 + fib 1
    ==. 2 ? fib2 ()
    *** QED
```

Unverified Operators All operators in ProofCombinators, but two are implemented in Haskell with implementations verified by Liquid Haskell. The "unsound" operators are the assume (1). (==?) that eases proof construction by assuming equalities, to be proven later and (2). (=*) extentional proof equality.
Assume Operator (==?) eases proof construction by assuming equalities while the proof is in process. It is not implemented in that its body is undefined. Thus, if we run proof terms including assume operator, the proof will merely crash (instead of returning ()). Proofs including the assume operator are not considered complete, as via assume operator any statement can be proven,
Function Extensional Equality Unlike the assume operator that is undefined and included in unfinished thus unsound proofs, the functions extensionality is included in valid proofs that assume function extensionality, an axioms that is assumed, as it cannot be proven by our logic.

To allow function equality via extensionality, we provide the user with a function comparison operator that for each function $f$ and $g$ it transforms a proof that for every argument $x, f x=g x$ to a proof on function equality $f=g$.

```
\((=*):: \operatorname{Arg} a \Rightarrow f:(a \rightarrow b) \rightarrow g:(a \rightarrow b)\)
    \(\rightarrow p:(x: a \rightarrow\{f x=g x\})\)
    \(\rightarrow\{f=g\}\)
```

The function (=*) is not implemented in the library: it returns () and its type is assumed. But soundness of its usage requires the argument type variable a to be constrained by a type class constraint Arg a, for both operational and type theoretic reasons.

From operational point of view, an implementation of (=*) would require checking equality of $f x=g \times$ forall arguments $x$ of type $a$. This equality would hold due to the proof argument $p$. The only missing point is a way to enumerate all the argument a, but this could be provided by a method of the type clas Arg a. Yet, we have not implement (=*) because we do not know how to provide such an implementation that can provably satisfy ( $=*$ )'s type.

From type theoretic point of view, the type variable argument a appears only on negative positions. Liquid type inference is smart enough to infer that since a appears only negative ( $=*$ ) cannot use any a and thus will not call any of its argument arguments $f, g$, nor the $p$. Thus, at each call site of (=*) the type variable 'a' is instantiated with the refinement type $\{v: a \mid$ false $\}$ indicating deadcode (since as will not be used by the callee.) Refining the argument x : a with false at each call-site though leads to unsoundness, as each proof argument $p$ is a valid proof under the false assumption. What Liquid inference cannot predict is our intention to call $\mathrm{f}, \mathrm{g}$ and p at every possible argument. This information is capture by the type class constraint Arg a that (as discussed before [55]) states that methods of the type class Arg a may create values of type a, thus, due to lack of information on the values that are created by the methods of Arg a, a can only be refined with True.

With extensional equality, we can prove that $\backslash x \rightarrow x$ is equal to $\backslash x \rightarrow$ id $x$, by providing an explicit explanation that if we call both these functions with the same argument $x$, they return the same result, for each x .

$$
\begin{aligned}
\text { safe }: & : \operatorname{Arg} a \\
& \rightarrow \text { a } \\
& \rightarrow(\backslash x \rightarrow \text { id } x)=(\backslash x \rightarrow x)\}
\end{aligned}
$$

```
safe _ \(=(\backslash x \rightarrow x)\)
    \(=*(\backslash x \rightarrow\) id \(x) \because(\exp ())\)
\(\exp :: \operatorname{Arg} a \Rightarrow a \rightarrow x: a\)
    \(\rightarrow\{(\backslash x \rightarrow\) id \(x) x=(\backslash x \rightarrow x) x\}\)
\(\exp \quad \mathrm{x}=\mathrm{id} \mathrm{x}\)
    \(==\). \(x\)
    *** QED
```

Note that the result of exp is an equality of the redexes $(\backslash x \rightarrow$ id $x) x$ and $((\backslash x \rightarrow x) x$. Extentional function equality requires as argument an equality on such redexes. Via $\beta$ equality instantiations, both such redexes will automatically reduce, requiring exp to prove id $x=x$, with is direct.

Admittedly, proving function equality via extensionality is requires a cumbersome indirect proof. For each function equality in the main proof one needs to define an explanation function that proves the equality for every argument.

### 1.2 Engineering Limitations

The theory of refinement reflection is fully implemented in Liquid Haskell. Yet, to make this extension usable in real world applications there are four known engineering limitations that need to be addressed. All these limitations seem straightforward to address and we plan to fix them soon.
The language of refinements is typed lambda calculus. That is the types of the lambda arguments are explicitly specified instead of being inferred. As another minor limitation, the refinement language parser requires the argument to be enclosed in parenthesis in applications where the function is not a variable. Thus the Haskell expression $(\backslash x \rightarrow x)$ e should be written as $(\backslash x: a \rightarrow$ $x$ ) (e) in the refinement logic,
Class instances methods can not be reflected. Instead, the methods we want to use in the theorems/propositions should be defined as Haskell functions. This restriction has two major implications. Firstly, we can not verify correctness of library provided instances but we need to redifine them ourselves. Secondly, we cannot really verify class instances with class preconditions. For example, during verification of monoid associativity of the Maybe instance

```
instance (Monoid a) => Monoid (Maybe a)
```

there is this Monoid a class constraint assumption we needed to raise to proceed verification.
Only user defined data types can currently used in verification. The reason for this limitation is that reflection of case expressions requires checker and projector measures for each data type used in reflected functions. Thus, not only should these data types be defined in the verified module, but also should be be injected in the logic by providing a refined version of the definition that can (or may not) be trivially refined.

For example, to reflect a function that uses Peano numbers, the Haskell and the refined Peano definitions should be provided

```
data Peano = Z | S Peano
{-@ data Peano [toInt]
    = Z
    | S {prev :: Peano}
    @-}
```

Note that the termination function toInt that maps Peano numbers to natural numbers is also crucial for soundness of reflection.
There is no module support. All reflected definitions, including, measures (automatically generated checkers and selector, but also the classic lifted Haskell functions to measures) and the reflected types of the reflected functions, are not exposed outside of the module they are defined. Thus all definitions and propositions should exist in the same module.

## J VERIFIED DETERMINISTIC PARALLELISM

Finally, we evaluate our deterministic parallelism prototypes. Aside from the lines of proof code added, we evaluate the impact on runtime performance. Were we using a proof tool external to Haskell, this would not be necessary. But our proofs are Haskell programs-they are necessarily visible to the compiler. In particular, this means a proliferation of unit values and functions returning unit values. Also, typeclass instances are witnessed at runtime by "dictionary" data structures passed between functions. Layering proof methods on top of existing classes like Ord could potentially add indirection or change the code generated, depending on the details of the optimizer. In our experiments we find little or no effect on runtime performance. Benchmarks were run on a singlesocket Intel® Xeon® ${ }^{\circledR}$ CPU E5-2699 v3 with 18 physical cores and 64GiB RAM.

## J. 1 LVish: Concurrent Sets

First, we use the verifiedInsert operation to observe the runtime slowdown imposed by the extra proof methods of VerifiedOrd. We benchmark concurrent sets storing 64-bit integers. Figure 18 compares the parallel speedups for a fixed number of parallel insert operations against parallel verifiedInsert operations, varying the number of concurrent threads. There is a slight observable difference between the two lines because the extra proof methods do exist at runtime. We repeat the experiment for two set implementations: a concurrent skiplist (SLSet) and a purely functional set inside an atomic reference (PureSet) as described in Kuper et al. [28].

## J. 2 monad-par: n-body simulation

Next, we verify deterministic behavior of an $n$-body simulation program that leverages monad-par, a Haskell library which provides deterministic parallelism for pure code [33].

Each simulated particle is represented by a type Body that stores its position, velocity, and mass. The function accel computes the relative acceleration between two bodies:

```
accel :: Body \(\rightarrow\) Body \(\rightarrow\) Accel
```

where Accel represents the three-dimensional acceleration

```
data Accel = Accel Real Real Real
```

To compute the total acceleration of $a$ body $b$ we (1) compute the relative acceleration between $b$ and each body of the system (Vec Body) and (2) we add each acceleration component. For efficiency, we use a parallel mapReduce for the above computation that first maps each vector body to get the acceleration relative to $b(a c c e l b)$ and then adds each Accel value by pointwise addition. mapReduce is only deterministic if the element is a VerifiedMonoid.

```
mapReduce :: VerifiedMonoid b }=>(\textrm{a}->\textrm{b})->\mathrm{ Vec a }->\textrm{b
```

To enforce the determinism of an $n$-body simulation, we need to provide a VerifiedMonoid instance for Accel. We can prove that (Real,,+ 0.0 ) is a monoid. By product proof composition, we get a verified monoid instance for

```
type Accel' = (Real, (Real, Real))
```

Fig. 18. Parallel speedup for doing 1 million parallel inserts over 10 iterations, verified and unverified, relative to the unverified version, for PureSet and SLSet.
which is isomorphic to Accel (i.e. Iso Accel' Accel).
Figure 19 shows the results of running two versions of the $n$-body simulation with 2,048 bodies over 5 iterations, with and without verification, using floating point doubles for Real ${ }^{1}$. Notably, the two programs have almost identical runtime performance. This demonstrates that even when verifying code that is run in a tight loop (like accel), we can expect that our programs will not be slowed down by an unacceptable amount.

## J. 3 DPJ: Parallel Reducers

The Deterministic Parallel Java (DPJ) project provides a deterministic-by-default semantics for the Java programming language [10]. In DPJ, one can declare a method as commutative and thus assert that racing instances of that method result in a deterministic outcome. For example:

```
commutative void updateSum(int n) writes R { sum += n; }
```

[^1]

Fig. 19. Parallel speedup for doing a parallel $n$-body simulation and parallel array reduction. The speedup is relative to the unverified version of each respective class of program.

But, DPJ provides no means to formally prove commutativity and thus determinism of parallel reduction. In Liquid Haskell, we specified commutativity as an extra proof method that extends the VerifiedMonoid class.

```
class VerifiedMonoid a m VerifiedCommutativeMonoid a where
    commutes :: x:a }->\textrm{y}:\textrm{a}->{x<>y=y<>x 
```

Provably commutative appends can be used to deterministically update a reducer variable, since the result is the same regardless of the order of appends. We used LVish [28] to encode a reducer variable with a value a and a region $s$ as RVar $s$ a.

```
newtype RVar s a
```

We specify that safe (i.e. deterministic) parallel updates require provably commutative appending.

```
updateRVar :: VerifiedCommutativeMonoid a ma m RVar s a m Par s ()
```

Following the DPJ program, we used updateRVar's provably deterministic interface to compute, in parallel, the sum of an array with $3 \times 10^{9}$ elements by updating a single, global reduction variable using a varying number of threads. Each thread sums segments of an array, sequentially, and updates the variable with these partial sums. In Figure 19, we compare the verified and unverified versions of our implementation to observe no appreciable difference in performance.
